From this description and drawing it is seen that on starting the drum an actinogram is the result, consisting of a series of bands, which are a quarter hour record of the light; taking them vertically, as in the ordinary actinometer, the intensity is given, whilst horizontally the length of time it was operative. Assuming the record to be printed on a film of gelatino-bromide, and developed with ferrous oxalate, or one of the non-staining developers, Abney's plan of measuring the transparency of negatives supplies a means of reading the actinogram within narrow limits, and covering a range of intensities much beyond the powers of a tint method. An instance will illustrate this: the scale of opacities I am at present using ranges, as measured, from 1 to 384; against this, on chloride paper, it is difficult to read differences greater than 1 to 150. In addition the readings are not so close, on a film transparencies as 1.3, 1.6, 2, 2.4, 3, are readily detected; on chloride paper the steps would be 5, 10, 20, 30. By this comparison the superiority of the silver bromide film and the Abney screen are evident.

My observations with films, however, are not yet complete, but, as through February, March, April, and May I have been making daily records with gelatino-chloride paper, I will explain the use of the actinometer, and the reading of the actinograms, by the aid of these experiments.

The scale in the actinometer consists of fourteen densities, and taking clear gelatine and glass equal 1, they run as under:—

1.0, 1.5, 2.3, 3.5, 7, 9, 15, 22, 50, 67, 110, 202, 307, 384.

The exposure is made in shadow, and at the end of the day I draw on the actinogram vertical lines one inch apart, marking each with the hour it represents. On squared paper I next write the hours along a base, and the relative opacities of the scale as vertical, fig. 2. A tint is then selected and traced through every hour, its position being marked on the squared paper; joining the points so noted the curve of the actinism is

FIG. 1.

create a false impression of the actinic values. To approach nearer to the real values, all actinometric readings should be continuous, the variations in actinism being recorded as an unbroken band.

In using silver-chloride papers for actinometric purposes, the initial difficulty is in the correct valuation of the amount of colouration. A very slight acquaintance with the subject will force on one that the degree of accuracy attainable is not high; and, likewise, with all observa-

FIG. 2.

secured; fig. 2 represents a typical April day, the 15th day of the month of the present year. The tint chosen in reading is one which falls on the verge of being invisible, though other and darker tints might also be utilised. By treating each day in the month in this manner its characteristic curve is produced, and at a future time the meteorological features of any day may be ascertained by referring to its actinic curve. Summing up, and finding the average of the light values from 8 a.m. to 4 p.m. at Bournemouth during April, I arrived at the figures in the table below, compared with which are values from Dr. Scott, the Rev. Dwight

W. Smith, and from Kew, for the same month. The figures are reversed values indicating relative exposures.

	Dr. Scott.	Rev. D. W. Smith.	K w.	Bournemouth.	Mean.
8 a.m.	1.6	2	3	2	2.1
9 "	1.2	1.5	1.8	1.4	1.4
10 "	1	1.2	1.3	1.04	1.1
11 "	1	1	1	1.07	1
12 noon	1	1	1	1	1
1 p.m.	1	1	1.2	1.02	1
2 "	1	1.2	1.5	1.2	1.2
3 "	1.2	1.5	2	1.7	1.6
4 "	1.6	2	2	3.2	2.4

The agreement between the figures is not complete, owing, perhaps, to the fact of their being derived in distinct ways, or to the influence of locality; the Kew figures and my own are both from silver chloride paper, and the most alike, except that I found the morning light much the more actinic. The mean of the four shows that my readings approach nearest to the probable actinic values.

After the change in actinism from hour to hour, comes that from day to day, fig. 3 is the curve for Bournemouth during April. The values were calculated by taking the mean of the nine readings from 8 a.m. to 4 p.m. Thus on April 1st the mean was 40, on the 13th, 80, on the 21st

Fig. 3.

only 15. Altogether the fluctuations from day to day are very great, sustaining the reputation of April as a changeable month. The very dull days were but three, the 4th, 21st, and 24th, whilst there were four days of exceptional chemical activity, the remainder being fine clear days of normal actinism. April 19 was a cloudless day, and may be taken as the normal for the month. The four bright days, 5th, 12th, 20th, 28th, were cloudy days, or rather, best described as "the sun seen through a light mist." By itself this actinogram is not so instructive as it would become in comparison with others from neighbourhoods less favoured than Bournemouth.

JOHN A. RANDALL.

#### ARTISTIC COPYRIGHT.

The following correspondence recently appeared in the *Standard*:—

"To the Editor of the '*Standard*.'"

"SIR,—In your report of my evidence on Artistic Copyright in the *Standard* of June 20, I am represented to have said to the Select Committee, 'If cheap reproductions were allowed, &c. Engravers have no objection to cheap reproductions provided they do not pretend to be expensive engravings and works of fine art. I should be sorry that process workers should think I had said anything so illiberal; it must have been a misunderstanding on the part of the reporter. As it is not unlikely to cause a lot of process workers to want to give evidence before the Committee, imagining that I had made an attack on them, complicating an already complicated affair, about which misunderstanding:

enough already exist, I trust you may kindly take an opportunity of setting the matter right in the *Standard*."

"Colourable imitations' only are aimed at in my paper, not legitimate process works.—I am, Sir, your obedient Servant,

"Newton Manor, Swanage, June 27."

"GERALD ROBINSON."

"To the Editor of the '*Standard*.'"

"SIR,—Mr. Gerald Robinson's letter in the *Standard* of this date fails to remove the impression produced upon the minds of process engravers by the evidence he is reported to have given before the Select Committee. He objects to the definition of engraving contained in the Bill as being too comprehensive, and as levelling any distinctions which now exist between artistic engraving and what he calls mechanical engraving. If he did not intend to include process engraving in the latter category, he certainly selected a very unfortunate expression; and, if he did include it, then process engravers have some reason to complain.

"The distinctions to be drawn between different methods of engraving are so subtle that they are capable of any amount of discussion; but, for the consideration of the purpose of this Bill, they are entirely irrelevant. Although the process-engraving industry is affected to a very considerable extent by the proposals of this Bill, the Association has not yet attempted to intervene, because it has recognised that the Bill is a laudable attempt to settle the whole question of artistic copyright on an equitable basis, and because it recognises the difficulty of reconciling so many conflicting interests. The greatest objection to it as drafted is that it does not make sufficiently for simplicity, and draws apparently unnecessary distinctions between original works of art and other artistic productions. A further objection is that in some cases copyright can only be conferred by registration, while in others registration is unnecessary except as a condition precedent to proceedings against infringement.

"As Mr. Robinson remarks, the question is complicated, but the complication is not likely to be diminished if an attempt is made to distinguish between different methods of engraving, to the detriment of the process worker.—I am, Sir, your obedient Servant,

"WALTER BOUTALL, Chairman.

"47, Lincoln's Inn-fields, London, W.C., June 29."

#### MAYALL'S SYSTEM OF DEVELOPING PRINTING-OUT PAPER.

THE well-known photographer, Mr. J. P. Mayall, whose works are at 10, Eye Hill-park, Peckham Rye, S.E., has for some time past been working at the problem of completing by development partly printed images on gelatine and collodion papers, and has met with an amount of success that has induced him to engage commercially in this branch of photographic printing.

It is not by any means the first time that this interesting process has been attacked with a view to rendering it amenable to regular adoption by photographers and trade printers; but, so far, it can hardly be said that the efforts expended have been followed by commercial, as distinguished from mere laboratory or experimental, success. We ourselves have produced pleasing single pictures by development of a partly printed-out image, but, in company with others, we have experienced the great difficulty of getting either regularity, uniformity, or variety of tone at will. In other words, development plus toning failed to yield the results obtained without difficulty by printing out plus toning.

Mr. Mayall claims to have overcome these difficulties, and the results he has submitted to us appear to bear out his claims. He showed us numerous specimens on developed collodion, gelatine, and albumen papers, and the tones of the prints were not only of the best photographic colours, but they have a wide range, and appear, by the number produced for our inspection, to be easily and uniformly obtainable. It is in the latter respect that the crux of the matter lies. Mr. Mayall offers to produce from a sample print any number of copies by development which shall match the original in gradation and colour. There should be a decided future for a developing process having these properties, for we and others have long contended that a reliable system of developing partly printed surface papers would be appreciated by professional photographers and trade printers.

#### THE AMERICAN INSTITUTE PHOTOGRAPHIC SALON.

MR. H. SNOWDEN WARD writes: "Enclosed I hand you a prospectus of a Salon to be held by the American Institute. This organization is (in its aims) a sort of hybrid between our British Association and our Society of Arts. It was established about 100 years ago, and in the early days of the century did a great work for American manufactures and applied

arts by the holding of exhibitions, giving of medals, &c. Latterly it has become simply a scientific and artistic society, having various sections (Electrical, Medical, Musical, Mechanical, Photographic, &c.), each holding its regular meeting independently of the other, and, as the Institute has considerable property, it has been accumulating funds. Some of its more progressive members have recently induced it to move from the premises it has occupied for the last few years to a building which they consider more worthy of its earlier traditions, and which provides some fine exhibition rooms. The Photographic Section considers itself fortunate and highly honoured by being allowed to manage the Exhibition with which the new rooms will be opened. For British workers the Committee has arranged a small British Committee of Selection, which will consider the works, and the American Institute undertakes that all works sent forward by that Committee will be hung without further selection, and they have also undertaken to pay carriage, duty, and all similar charges from London to New York and back again. I think, therefore, they have done everything possible to meet British wishes, and, as they have asked me to undertake a portion of the correspondence for them, I am naturally anxious that their Exhibition should be a thorough success. You will see from the prospectus that no awards are offered except a certificate of acceptance for every one whose work secures a place. This certificate will be executed in photogravure, and will be an exceedingly handsome thing. There is no feeling of rivalry or competition between the Salon of the American Institute and that which is being arranged by the Philadelphia Photographic Society. The date of the New York Exhibition was necessarily fixed by the date of the opening of the Institute's new premises, and the Exhibition was decided upon at a time when it was not expected that the Philadelphia Salon would be repeated this year. It is unfortunate that the dates prevent the pictures being sent from the Philadelphia to the New York show, but this seems impossible, as the time between the closing of the former and the opening of the latter is too short for hanging, cataloguing, &c. Copies of the prospectus will be sent to secretaries of societies, or to would-be exhibitors, who may write for them."

#### THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM, GLOUCESTER, 1899.

The following is the synopsis of next week's proceedings:—

**MONDAY, JULY 10:** Excursion to *Elmore, Fretherne, and Frampton-on-Severn*.—Trains leave head quarters at 12 noon; lunch at Bell Hotel, Frampton, at 2.30. At the Guildhall, at 7.30, official opening of the Convention by the Mayor, after which the new President (Mr. W. Crooke) will deliver his Presidential Address, followed by a "Demonstration of Colour Photography," by Mr. R. Child Bayley, and an exhibition of specially selected lantern slides.

**TUESDAY, JULY 11:** Excursion to *Berkeley and Berkeley Castle*.—Trains leave Midland Station at 10.0 and 10.55; luncheon at Berkeley Arms Hotel, at 2.30; return trains from Berkeley Station at 3.15 and 5.22, arriving in Gloucester at 4.0 and 6.40. At the Guildhall, at 8 a paper on "Fundamental Points concerning Development," by C. H. Bothamley, followed by an exhibition of lantern slides by members of the Gloucestershire Photographic Society.

**WEDNESDAY, JULY 12:** Members will be officially conducted over the Cathedral at 2.0. *Note.*—The Dean has kindly given permission for the members to photograph the interior of the Cathedral at any time during the meeting, except during the hours of Divine Service. At the Guildhall, at 10.0, the Annual General Meeting and election of Council for the ensuing year. At the Spa Cricket Field, at 12 noon, the official Convention Group will be taken. At the Bell Hotel (head-quarters), at 7.0, Annual Dinner and Smoking Concert.

**THURSDAY, JULY 13:** Excursion to *Chepstow, Tintern, and Symonds Yat*.—Trains leave Great Western Station at 9.29, arriving at Chepstow at 10.20. *Note.*—Luncheon will be provided at Chepstow for those members who have arranged to drive over the Wyndcliffe to Tintern. A special train leaves Chepstow at 12.30, arriving at Tintern at 12.45; luncheon at Beaufort Arms Hotel, Tintern, from 1.0. Trains leave Tintern at 3.8 and 6.51, arriving at Symonds Yat at 3.52 and 7.36; train leaves Symonds Yat at 8.33, arriving in Gloucester at 10.0. There will be no meeting at the Guildhall on Thursday evening.

**FRIDAY, JULY 14:** Excursion to *Ashleworth, Deerhurst, and Tewkesbury*.—The steamer *Avonmore* will leave Westgate Bridge at 9.30. The times of the steamer's departure from Ashleworth, Deerhurst, and Tewkesbury will be announced on arrival at each of these places. Luncheon will be served on board after leaving Deerhurst. At the Guildhall, at 8.0, a paper on "Binocular Vision and the Stereoscope," by Mr. Thomas Bedding, F.R.P.S., and "Wordsworth Country," by Percy Lund, followed by an exhibition of specially selected lantern slides.

**SATURDAY JULY 15:** Various short excursions to places in and around Gloucester will be arranged as may be required. Among those easily accessible are Highnam, Matson, Hempstead, Cheltenham, Ledbury, Forest of Dean, &c. Members will oblige by signifying their wishes to the Hon. Secretaries as early as possible, in order that satisfactory arrangements may be made for the desired excursions, and particulars duly posted on the notice board.

## Our Editorial Table.

### THE "STEREOSCOPIC" BINOCULAR CAMERA.

W. Watson & Son, 313, High Holborn, W.C.

We have examined this clever binocular camera and several transparencies printed from negatives obtained in it, and were very pleased with the instrument itself and the excellent stereoscopic results it is capable of yielding. In use, the instrument points in one direction, but the view taken is that in another, namely, to the left of the photographer, hence the camera is really a "detective" one. The following extracts from the instructions for use give the reader a good idea of the principles upon which the camera is constructed:—

"The camera is held to the eyes in precisely the same way as a field glass, but care must be taken that the left hand does not obstruct the angle of view of either of the two lenses.

"The view to be taken is seen in a finder provided and placed in the left tube of the camera; it is in exactly the same plane as the lenses.

Sectional View, showing Position of Plates.

"Changing the Plate.—After an exposure has been made, first record it in the numbered disc, revolving in the eye end of the camera; then open the back, *r*, pull out the bag and draw, by means of the projecting ring, the exposed plate into the bag. This plate is then replaced in the back of the magazine.

"When twelve plates have been exposed and changed to the back of the magazine, there remains in front an aluminium sheet, which, by keeping the magazine light-tight, enables it to be drawn out in daylight and another magazine inserted. Before the magazine can be drawn out, the clamping screw must be loosened and screwed up again after the magazine is replaced.

"No focussing is required, all objects from six feet to infinity being focussed sharply on the plate."

The sectional view gives a good idea of the construction of the camera, which presents the appearance of a pair of handsome field glasses. For taking stereoscopic photographs of people unawares, it is a clever arrangement, the real object of which is well calculated to deceive the multitude.

### "AGFA."

A. & M. Zimmermann, 9 and 10, St. Mary-at-Hill, E.C.

We described the salient characteristics of Agfa in the *JOURNAL* a few weeks ago, and a practical trial with a sample bottle that we have since received enables us to confirm the claims made on its behalf. Agfa, so far as we can judge, is a really good and useful intensifier, which many a photographer will appreciate. Being colourless, it is cleanly to work with, and it is certainly a very great convenience that it enables intensification to be effected straight away—that is to say, it is not necessary to follow it with a blackening solution. There is the further point in its favour, that it may be used for positives as well as negatives.

### AURIA SELF-TONING PAPER.

G. Houghton & Sons, 89, High Holborn, W.C.

THERE appears to be a considerable demand for silver printing-out papers of the self-toning kind which only require fixation and washing to complete the image. Auria is a collodion paper, issued with glossy and matt surfaces, both papers giving tones which leave nothing to be desired in the way of agreeable colour, purplish tones with the glossy and sepia

with the matt being their characteristics. The following are the instructions for working:—

**Printing.**—Print a shade darker than desired in finished prints, using tissue paper if printing in the direct sunlight.

**Fixing.**—Prints may be put direct from the printing frame into the hypo bath, but, to prevent getting spots in the finished prints from air bubbles, &c., it is advisable to first place the prints in clear water until thoroughly soaked, and then into the fixing bath, consisting of 1 ounce of hyposulphite of soda (crystals) and 20 ounces of water, hydrometer test 20. Then wash in running water until the hypo is entirely removed; this takes about an hour. If running water is not available, at least eight changes of clear water should be used.

**Burnishing.**—Prints on this paper can be burnished in the same way as any other papers. For matt-surface paper, of course, a cold burnisher should be used.

**For Platinum (Black-and-White) Effects.**—Print several shades darker than desired in the finished print. Wash the prints in three changes of clear water, and then place them in any good platinum bath until the reddish-brown disappears from the deep shadows. After this, give one wash in clear water, and then place in hypo solution, as above directed.

#### THE "AXE" BRAND P.O.P. AND BROMIDE PAPERS.

Fuerst Brothers, 17, Philpot-lane, E.C.

UNDER the above designations Messrs. Fuerst Brothers are introducing two new printing papers. They inform us that the P.O.P. is made in two grades, viz., "Brilliant," for soft negatives, and "Soft," for hard negatives. The glossy surface is made in the following colours: white,

pink, and mauve, and matt surface in white only. The platino-bromide paper is made in three grades, viz., A, B, and C. A, matt surface, or contact printing, smooth or rough; B, matt surface, for enlargements, smooth or rough; C, glossy surface, for contact printing or enlargements, thick or thin. The matt surface paper can be supplied extra thick for post cards, &c., if required.

RECEIVED: *Corriere Letterario della Libreria Antiquaria di U. Hoepli*, 7, Corso Vittorio Emanuele, Milano. Many standard photographic books are included in this list, which might be worth the while of book collectors to apply for.

## News and Notes.

PHOTOGRAPHIC CLUB.—July 12, at eight o'clock. Members' Open Night.

Mr. L. A. COCKWR, M.P.S., of 63, Mostyn-street, Llandudno, informs us that he has erected a dark room for the use of visitors.

THE new Hon. Secretary and Treasurer of the London and Provincial photographic Association is Mr. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

VISITORS to the Convention may wish to avail themselves of the facilities offered by the Cathedral Photographic Depot, 7, College-street, Gloucester, which has a dark room, supplies of material, &c.

A BOOK of *South African Portraits* is published by Messrs. Frederick Warne & Co. It contains no fewer than 120 reproductions (with biographical etches) from photographs taken by Messrs. Elliott & Fry, beginning with Queen, Sir Alfred Milner, and Mr. Chamberlain.

Messrs. JOHN H. AVERY & Co. have recently established themselves as photographers at 164, Strand, W.C. Mr. Avery's forte, it is well known, is architectural photography, a branch in which he has achieved many conspicuous successes. We wish the new firm a prosperous career.

SOME satisfactory photographic results were obtained last week from Mr. Spencer's balloon, which ascended from the Crystal Palace. The aeronaut, accompanied by Mr. Frank Foulsham and Miss Gladys Tussell. The atmosphere was clear, and good views of the Tower Bridge, Isle of Dogs, Greenwich Hospital, Royal Observatory, and Victoria and Albert Docks were obtained.

CHANGES AT THE SCIENCE AND ART DEPARTMENT.—Major General Sir John D. Donnelly, K.C.B., has retired from the Secretaryship of the Science and Art Department, and in consequence the Duke of Devonshire (Lord President of the Council) has made the following appointments: Sir George W. Keble, the present Secretary of the Education Department, to be also Secretary of the Science and Art Department; Captain W. de W. Abney, C.B., to be Principal Assistant Secretary of the Science and Art Department; Mr. W. Abney, C.B., to be the Principal Assistant Secretary of the Education Department.

THE new schedule has been issued for the "One and All" Flower Show, to be held at the Crystal Palace in August, in connexion with the Annual Co-operative Festival. The schedule this year is in two parts, forming two illustrated pamphlets, running into about 140 pages, and containing offers of prizes calculated to stimulate every kind of horticultural excellence amongst working men, women, and children throughout the kingdom. The photographic classes have been extended to thirty-four in number, and are this year divided into two sections, the first of which will be judged from a horticultural point of view, and the second by their artistic merits as photographs. Copies of either schedule may be obtained free of charge from the Hon. Secretary, Mr. Edward Owen Greening, at 8, Agar-street, Charing Cross, W.C.

CHEAPENING LIQUID AIR.—Dr. Ostegren, of New York, who has made exhaustive experiments with liquid air, announces that he has invented an apparatus, which, when tested in the presence of expert witnesses, proved equal to turning out liquid air at the rate of 1500 gallons daily. The product registered 400° below zero. It can be made at a cost of five cents per gallon. The basis of Dr. Ostegren's present apparatus is a steam engine of 100 horse power. He believes that, with a more modern engine, he could produce liquid air at two cents per gallon, at which price he could enter the market with a view to the wholesale exportation of liquid air, both as a refrigerant and as a motive power. Coincidentally with Dr. Ostegren's discovery, Mr. Brady, of Chicago, announces that he has patented a cask in which liquid air may be safely carried.—*Laffan*.

PHOTOGRAPHERS SENT TO GAOL.—At the Lindsey Quarter Sessions, on Friday, June 30, Robert Audas, aged forty-three, photographer, and Frederick William Hart, aged thirty-four, photographer, were charged with feloniously stealing 14. 1s., the moneys of William Brown Nicholson, of Northorpe, on April 22 last, and also with stealing 10s., the moneys of Robert Morris, of Scotton, on April 25 last. The charge of obtaining the 10s. from Morris was first gone into. The prosecutor stated that he was a farmer at Scotton, and on April 25 the prisoners, who were apparently travelling the country and taking photographs, presented themselves at his house, and suggested that he should have his house and family group taken. He eventually agreed to have a family group taken outside the house. After the photograph had been taken, it was suggested that payment was necessary, and he parted with 10s. to the prisoners, for which he received a receipt. The men then went away, but the proofs did not arrive. Mr. Morris wrote, making inquiries, but received no reply. For two months nothing more was heard of the prisoners, but on June 16 Mr. Morris received the proofs; however, that was after prisoners had been arrested on another charge. Counsel, on behalf of the prisoners, said the question for the jury to decide was whether there was any intention on the part of the prisoners to supply the photographs in the first instance. For the defence, it was contended that the transaction was a *bona fide* one, but that some delay took place in executing the orders, owing to the weather. Delay in executing an order was not proof of intention to defraud. The prisoners were eventually found guilty and sent to gaol for four months with hard labour each.

## Patent News.

THE following applications for Patents were made between June 19 and June 24, 1899:—

PROJECTION APPARATUS.—No. 12,835. "Improvements in and relating to Stop Mechanism for Photographic Cameras, Projectors, and the Like." Complete Specification. W. STEVENS and W. S. BELL.

AUTOMATIC APPARATUS.—No. 12,846. "Improvements in Automatic Photographic Apparatus." J. E. GREGORY.

CAMERAS.—No. 13,152. "Improvements in or relating to Photographic Cameras." A. I. ADAMS.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
11.....	Birmingham Photo. Society	Presentation of Prizes awarded at the Annual Exhibition, by the President.
11.....	Hackney	"Dekko" Printing. A. E. Robins.
12.....	Photographic Club	Members' Open Night.
13.....	Hackney	Excursion to Cheshunt. Leader, H. J. Webb.
14.....	Croydon Microscopical	Conversational Meeting.
15.....	Borough Polytechnic	Excursion: Hayes and Keston Commons. Leader, W. Mundy.
15.....	Croydon Microscopical	Excursion: Coulsdon, Chaldon, White Hill, and Caterham. Leader, A. J. Hogg.
16.....	South London	Sunday Excursion.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 29.—Annual Meeting.—Mr. H. Vivian Hyde in the chair.

The retiring HON. SECRETARY (Mr. T. E. Freshwater) read the annual report, as follows, with the balance-sheet, which were duly adopted:—

In presenting the annual report of this Association I think we may congratulate ourselves upon a successful and useful session. Neither in the attendance of members nor in the interest shown in our papers and discussions has there been any falling off; and, if I may be allowed to say it, I think

a more correct idea of a photographic society's position is to be gleaned from the general and continuous interest week by week than by one or two very special evenings during a year with the rest more or less unimportant. We have to find something every week that will prove useful and instructive, and I think the reports of our meetings in the photographic press will amply prove that during the year just ended we have been able to keep the ball rolling most effectively.

I believe, too, that some of the newer or younger members have come more to the front, and taken their share in our proceedings. The more this is done, the better for our Association. In my last report the younger members were appealed to for papers, &c., and, although they may not have come forward in this respect as much as we should like, yet they have rendered assistance in the discussions and taken part in the management.

The following is a list of the papers read, demonstrations given, or discussions opened; but, in connexion with this, it must be remembered that, during the months of July and August last, no programme was made up, and no formal papers read, but the objects of interest shown and the discussions upon various topics during those two months were, nevertheless, ample substitutes. It was during this period that the prolonged discussion upon "The Exposure in Shadow and Diffused Light" took place, and this formed the subject of our first formal paper:—

"Exposure in Shadow and Diffused Light," Mr. Walter D. Welford. "Soda Formate Toning," Mr. A. L. Henderson. "Standards and Uncharitableness," Mr. Walter D. Welford. "Pyro-soda Development," Mr. Ben Edwards. "Forty Years Ago," Mr. S. Herbert Fry. "Rapid Plates versus Slow," Mr. W. T. Wilkinson. "Birch and Bracken," Mr. W. Thomas. "Phosphorescence in Relation to Photography," Mr. C. F. Townsend. "Lantern Experiments Relating to Colour," Mr. T. E. Freshwater and Mr. E. J. Wall. "Novitas Stripping Film P.O.P. and a New Method of Toning Silver Prints," Mr. Otto Scholzig. "Abolishing the Dark Room," Mr. Howard Farmer. "Development of P.O.P.," Mr. T. E. H. Bullen. "Photographic Society Life," Mr. Walter D. Welford. "Intensification and Reduction," Mr. John McIntosh. "Chat on Photographic Lenses," A. T. Harris. "Photographing Insects," Mr. T. E. Freshwater. "Modern Hand Cameras," Mr. J. E. Hodd. "Exposure and Development," Mr. W. T. Wilkinson. "Exhibitions, Technical and Otherwise," Mr. R. Child Boyley. "Important Photographic Problems," Mr. Herbert S. Starnes. "Modern Photographic Lenses," Mr. T. E. Freshwater. "Stereoscopic Photography," Mr. J. E. Hodd. "The Past Year and the Future," Mr. Walter D. Welford.

As regards Lantern Nights, the past year has been quite up to the standard, and we have had the following interesting lectures: "Corsica," Mr. A. L. Henderson. "The Cumberland Fells," Mr. Walter D. Welford. "My Visit to America," Mr. H. Snowden Ward. "Palestine and Turkey," Mr. P. R. Simmon, whilst some excellent slides have been shown by Messrs. Fry, Medland, Teape, Freshwater, Tom Bright, Bullen, Rapson, Ben Edwards, and others.

During the year we have had two special events, to which reference must be made. On February 9 there was the Supper, at which seventy members and friends were present. It was somewhat of a venture or experiment, but the result proved its popularity and success. It brought amongst us some old and good members, whose presence we should like oftener. A most enjoyable evening was spent, and every one appeared to appreciate the efforts of the little committee that engineered it. We have also to thank Mr. Henderson for his hospitality and kindness to us upon our recent visit to his residence at Brimsdown.

It will be seen from the list of papers read, lantern lectures, &c., that the number reaches twenty-six, so that once a fortnight we have had a formal paper or lecture, to say nothing of the many interesting communications made to, and discussions got up by, the Association.

As regards the number of members, there has been a fair number of new men elected, but not so many as one would wish. Some of the old members have gone away, and I wish to impress upon all the absolute necessity of keeping up the numbers by getting new men to join our ranks.

By the balance-sheet that I have had the pleasure to present to you, you will see that we have plenty of money in hand, and that our income has been considerably more than our expenditure, which was not the case last year.

The following is the result of the election of officers and Committee for the ensuing year:—*Trustees*: Messrs. A. Haddon and J. B. B. Wellington. *Committee*: Messrs. R. Bickett, R. P. Drage, T. E. Freshwater, S. H. Fry, J. E. Hodd, H. Vivian Hyde, A. Mackie, and J. S. Teape. *Librarian*: Mr. E. T. Wright. *Curator and Lanternist*: Mr. Haskins. *Recorder*: Mr. J. W. Hoiges. *Hon. Secretary and Treasurer*: Mr. Walter D. Welford.

Votes of thanks were passed to the retiring officers and Committee.

Mr. S. H. Fry presented a framed enlargement from one of Mr. Henderson's negatives, taken on the occasion of the recent outing to that gentleman's house at Brimsdown, for which he was accorded a vote of thanks.

Several other prints taken at the same time were passed round by the members.

Mr. J. E. Hodd showed a hand camera fitted with Sanderson's rising front. Mr. Philip Everitt showed some further trials of the new Platona paper. Reference to last week's report shows that the phosphate of potash prescribed had not been used, but Mr. Everitt now brought forward results comparing Platona paper developed with oxalate and phosphate respectively, and both with platinotype paper. He drew attention to certain mottled marks on a Platona print, and mentioned that he had ascertained the cause to be the withdrawal of the print from off the bath before it was fully developed. If allowed to remain until the image was completely out, the defect would not appear. Phosphate seemed to yield a colder tone with the Platona paper than did the oxalate.

#### PHOTOGRAPHIC CLUB.

JUNE 28.—Mr. H. Vivian Hyde in the chair.

Mr. E. W. FOXLEE showed some photographs by Mr. A. S. Whitcomb, of Buenos Ayres, which had been sent over for exhibition, at the request of the

President of the Argentine Republic, at the recent bazaar at the Albert Hall. Mr. Foxlee thought the examples, which comprised portraits and groups varying from cabinet size to 20 x 16 direct, spoke well for the status of photography in South America. They were on matt-surface collodio chloride paper of Mr. Whitcomb's own preparation, and he found that this style took very well indeed with his customers, his work being now largely executed therein.

Mr. H. SNOWDEN WARD, in reference to a remark upon the greater difficulty of getting orders for large direct work than in executing it, said that for years the cabinet had been the smallest print made in the States professionally, and that large direct photographs, such as those shown, were much favoured.

A number of slides were subsequently seen upon the screen, being some sent in for display at Convention meetings at Gloucester, and Messrs. Bridgman, Bridge, and Wellington passed judgment thereon as the Selection Committee.

**Ashton-under-Lyne Photographic Society.**—This Society had an excursion to Llangollen on Saturday. Mr. Charles Lord was the leader and provider—a sort of earthly providence. The "engaged" carriages had on them "Mr. Lord's excursion," and some irreverent individual perpetrated the unhallowed joke, "The train is the Lord's and the fulness thereof." That, however, was only partly true, for many other excursion parties to the same destination were hooked on to the same train at Chester, and quite an extraordinary number turned out when the train stopped at Llangollen. It is a very fine place for a day trip, not too far to go, and not too much to do when you get there. The hills are not big enough to break your neck if you look up to their tops from the valleys, and, if you want to get to the summit, it is not a business of half a day to get there and back. Then, whichever way you turn, you are charmed with the beauty of the scenery, with the green and well-wooded hills all round, the rocky river bed, the curious old bridge, and the umbrageous walks in all directions. The weather was all that could be desired, except that for the photographers the wind ruffled and rustled the trees too much. On the journey home the party were informed at Chester that they had missed the connexion, and would have to wait forty minutes. The carriages were left standing on the interior line of rails, so that the passengers could not get to the platform without crossing another line of rails and getting helped up to the platform. Many preferred to get out, and went to have a walk about the old city. When they returned at ten minutes to nine, they found that their engaged carriages had gone half an hour before with their cameras and other belongings. Others were informed before they left the station that the carriages would be taken forward by an earlier train, and they returned in time to resume their seats. The upshot of these proceedings was that the photographers did not all arrive in Ashton at the same time, but by three different trains, some before eleven, some after eleven, and some after twelve. No doubt some of them have had a good deal of seeking to recover their stray cameras.

#### FORTHCOMING EXHIBITIONS.

- 1899.
- Sept. 22–Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- " 25–Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18–24 ..... Croydon Camera Club.
- " 22–Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27–Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7–9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

#### Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM: GLOUCESTER MEETING—CHEAP EXCURSIONS.

To the Editors.

GENTLEMEN,—Members from London may be glad to avail themselves of the following excursions:—

From Paddington for Gloucester, Friday, July 7, at 4 2 p.m.; Sunday July 9, at 8.15 a.m.; Monday, July 10, at 8 a.m.

Tickets available to return by the train leaving Gloucester at 6.20 p.m. on either July 13, 17, 20, or 24: ten shillings for the double journey.—I am, yours, &c.,  
F. A. BRIDGE, Hon. Secretary and Treasurer.  
Gloucester address, Wellington Hotel.  
East Lodge, Dalston-lane, London, July 1, 1899.

## CELLULOID MEASURES.

To the EDITORS.

GENTLEMEN,—I was sorry to see in your remarks, page 392, your views in justification of the British manufacturers not placing celluloid measures on the English market. They are made in Germany and sold in large quantities. I have one, and I find it exceedingly useful and quite accurate enough for all ordinary purposes. No one with any pretensions to a knowledge of chemistry would think of measuring ether, &c. in a celluloid measure than they would measure fluoric acid in a glass vessel. I am not a believer in the "conscientiousness" of the British workmen. Another case came under my notice. A manufacturer was asked for a quotation of a small quantity of an elastic substance drawn out like wire used here by surgeons as probes and made in Germany; they replied that "they would not make less than three cwt., and then they would not guarantee that it would answer the purpose."

Very conscientious of them. I hope that the question and want may catch the eye of some German or American manufacturer, and before long we will have them in the English market in English measure. They should be of cylindrical form without feet and nested say from one to ten ounces.—I am, yours, &c.,  
A. L. HENDERSON.

## DEVELOPING SPECTRUM AND PANCHROMATIC PLATES.

To the EDITORS.

GENTLEMEN,—An obstacle to the use of these plates is the supposed necessity of using either a special safe light in the dark room or an exceedingly feeble one. I have, however, used many of these plates during this season and last for colour and other photography, and have never used a dark-room light at all with them, but have yet secured complete control of results with ease and comfort. It is done by testing the developer beforehand with a trial slip, and then timing development by the appearance of this.

I shall be at the Gloucester Convention next week (except on Wednesday) and hope to give a short dark-room demonstration of the method, at such time or times as may be convenient, to interested persons.—I am, yours, &c.,  
ALFRED WATKINS.

Hereford, July 1, 1899.

## PHOTOGRAPHY IN DOTS.

To the EDITORS.

GENTLEMEN,—By the courtesy of one of your readers, Mr. Batten, of this town, I have had my attention drawn to the communication of Mr. F. G. Willatt in a recent number of your JOURNAL, and supposing that probably the subject brought forward by him may be deemed of considerable interest to many of your readers, I would venture to suggest that the "evolution" of an improved and workable grained screen, as forecasted in Mr. Willatt's communication is already a *fait accompli*.

With this I am enclosing a print grained by the placing of a "metzograph" screen over but not actually touching the negative used for the printing, such negative, however, exhibiting the marks of previous retouching. Mr. Batten is preparing more suitable prints prepared both to show the results of the screen when used either for printing or within the camera for imparting a "metzo" grain to the negative, either for studio or process work.

As, however, it is the more novel features and advantages offered by "metzograph" screens that I would ask leave more particularly to bring under your notice, I would remark that, together with a grain of any desired fineness, by my process there is compassed the desideratum of both an ungeometrical and sufficiently regular distribution of the size of the grain.

Further, as concerning the absolute novelty of the mode of preparing these screens, I have no doubt that will be deemed sufficiently obvious on perusal of the description of the analogous procedure in the preparation of Listulin dressings as set forth in the accompanying paper.

I would add that my patent, embodying both the first sublimation of betulin direct from birch bark, and utilisation of same for various purposes, is, in this country, No. 12,017, of 1897, and entitled, "Improvements in the production of coatings or films, on glass and other articles or materials, and in apparatus therefor."

In conclusion, I would say that, in addition to the specimen prints referred to in the foregoing, it would afford me much pleasure to send a set of screens for your acceptance so soon as I have provided myself with glass of more suitable character, my experiments thus far having all been worked out with ordinary sheet glass, which, having minute

scratches occasioned by the straw packing used, the same become accentuated on etching, and so constitute blemishes.

Soliciting your kind inspection of the specimens, I am, yours, &c.,  
100, High street, Ilfracombe, June 27, 1899.  
J. WHEELER.

[We are very much obliged to Mr. Wheeler for his interesting letter and the specimens produced by his metzograph screens. The precise method adopted by Mr. Willatt in the preparation of his irregularly grained screens is unknown to us, but the results they yield differ from those sent by Mr. Wheeler. The latter have an exceedingly fine grain, whereas Mr. Willatt's results are comparatively coarse and "broad" in effect.—EDS.]

## THE PHOTOGRAPHIC SALON.

To the EDITORS.

GENTLEMEN,—I shall be much obliged if you will kindly intimate in the next issue of your valuable paper that applications for entry forms for the Photographic Salon should be addressed to me here, and not to the Dudley Gallery.—Thanking you in anticipation, I am yours, &c.,  
Camera Club, Charing Cross-road, W.C.  
June 30, 1899.  
REGINALD CRAIGIE.

## IN REPLY TO "FREE LANCE."

To the EDITORS.

GENTLEMEN,—I sincerely congratulate "Free Lance" upon the progress he has made since June 16. He is emerging from his archaic notions of art, and may some day produce a picture instead of a map.

Our knight errant must have been deeply disappointed to find his favourite Rozinante of no use as a racer. The necessities of the situation may account for his difficulty in distinguishing between the head and the tail of the animal.

If "Free Lance" will study the command a planar lens and a focal-plane shutter will give him in instantaneous photography, he will find that the remark I made is nearer the truth than he supposed.—I am, yours, &c.,  
July 3, 1899.  
P. EVERITT.

## A CORRECTION.

To the EDITORS.

GENTLEMEN,—In the report of the North Middlesex proceedings in your last issue are one or two inaccuracies.

The discussion was quite informal, and the reporter has credited me with some statements made probably by some one else, which is not surprising under the circumstances.

For instance, I am not responsible for the statement that false gradation would be introduced into a stripped and reversed negative, nor for the other statement that metal would stain in development.—I am, yours, &c.,  
J. MCINTOSH.

14, Lowman-road, Holloway, July 1, 1899.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

F. C. MacMahon, 23, Academy-street, Liverpool, N.B.—Photograph of (St. Mary's Lodge) Freemasons' group, Liverpool.

B. Pearce, Empire Studio, Machynlleth, County Montgomery.—Photograph of group of representatives of first Welsh Wesleyan Methodist Assembly.

"J. W. D."—Impossible for us to trace him.

A. G. BROPHY.—1. We are much obliged for your suggestions, which we will bear in mind. 2. F-11, approximately.

GLENBROOK.—If the photograph is copyright in Russia, it is, *ipso facto*, copyright here, and its reproduction is attended by the risk of an action for infringement.

BILTON.—1. Such a negative will do for the process. 2. The same as for the ordinary collotype process. 3. Yes; we have seen really good results produced by it.

COLOURING PHOTOGRAPHS.—F. DANKS writes for list of publications in reference to same, or short description of various ways of doing, &c., colours required, &c.—Messrs. Newmann & Co., 5, no square, publish a work on the subject.

**PATENT.—HERTS.** If the apparatus is patented, it would be illegal for you to make it. The mere fact that you made it yourself, and exclusively for your own use, makes no difference, you infringe the patent all the same.

**DRY FERROTYPED PLATES.—E. WILLIAMS** asks: "Will you kindly tell me the names and addresses of the makers of dry ferrotyped plates and oblige?"—In reply: These may be obtained of Fallowfield, 146, Charing Cross-road, W.C.

**W. H.** says: "Can you tell me if the improved Dixie vignetter can be obtained in England? The Scovill & Adams Company are the New York agents."—We think not. It would be necessary for you to order it through a dealer.

**METOL FOR VELOX.—AMATEUR** asks: "Can you tell me correct way to mix metol developer for Velox paper? I mixed all ingredients before and the result was failure."—Simply mix the developer according to the formula issued with the paper. If that is done, there will be no failure.

**ENAMELLING P.O.P.—GLOSSY** says: "I should esteem it a favour if you would give me a formula for producing a very highly glazed surface on P.O.P. prints (raised enamelled)."—See reply to "Brilliance." Attach one or more thicknesses of paper to the back of the print while on the glass and before it is dry.

**COPYRIGHT.—W. H.** says: "If I take a portrait of a person as an order, and he pays me for so many cabinets, can I, with his consent, copyright the photograph in my own name? I shall have his consent in writing."—In reply: In order that you should become possessed of the copyright, it should be assigned to you in proper legal form.

**TONING BATH WANTED.—R. A. BEEMAN** says: "Will you kindly inform me in your next issue of a good toning bath for sepia bromides developed with amidol?"—The method usually employed for sepia tones on bromide paper, whatever the developer, is the well-known uranium toning method. We know of no better for bromide prints.

**COPYRIGHT.—PERPLEXED** says: "I have just photographed a curiosity, for which I have made no charge. Can you inform me if I have any copyright in the portrait without having the same registered?"—In reply: The copyright is yours. You had better register the photograph. Our publishers will effect same for you if you will send them three prints and 1s. 7d. in stamps.

**THE FACTORY ACT.—APPRENTICE** says: "In our workshop there are five of us, two of that number apprentices. Does our place come under the Factory Act? I may state that we have only two holidays in the year, Christmas Day and the general holiday."—We should say that the workshop does come under the Factory Act, particularly if all the hands employed are "young people."

**MARKED PLATES.—D. STUART** sends us some prints from negatives made in a new camera which have a mark across them, and asks us to account for the defects. The negatives, he says, were made on —'s plates.—The marks are clearly due to emanations from the hinge fabric of the shutters of the dark slides. The remedy is to replace the present fabric with an inert material. This the camera-maker should do.

**STEREOSCOPIC CAMERA.—C. R. B.** says: "I am designing a stereoscopic camera I am going to have made. Will you please tell me if there is any necessity to have the lenses adjustable, or will a fixed distance of two and three-quarter inches suffice?"—We should prefer to have the lenses adjustable, say, from two and a half to three and a half inches apart, the latter distance for when there are no near objects in the foreground.

**VALUE OF COPYRIGHT.—AMATEUR.** We cannot assess the value of the copyright. As the firm want the photograph to reproduce for advertising purposes, they will, doubtless, pay a good price for it. Under the circumstances named, we should say they would pay ten guineas for the copyright—possibly more. We know that the same firm have paid higher sums than that for copyrights. Our advice is, Get as much as you can.

**ENAMELLING PRINTS.—BRILLIANCE** writes: "Kindly give brief directions for enamelling gelatine prints with collodion, and say if they will adhere to the collodion by reason of their own gelatine (unalumed), or require to be covered with adhesive?"—Thoroughly clean the glass, and then treat it with French chalk. Coat with collodion, and wash until all greasiness disappears, then squeegee the print upon it. With most papers that is all that is necessary. With some, however, it may be necessary to immerse the plate and the print in a dilute solution of gelatine before squeegeeing the print upon the collodion surface.

**PHOTOGRAPHY.—INTAGLIO** says: "Can you give me any information as to—(1st) the name, (2nd) the probable cost, and (3rd) number of copies per day of a steam, or other power, photogravure press, such as is used for the Rembrandt process? I have heard of one with an Italian-sounding name, but should be pleased to know where full information can be obtained about it."—If our correspondent refers to the Rembrandt Photographic Company, we cannot say. We believe the process is worked by the Company as a secret one, and no details of the method have been published. Possibly some reader will supply the desired information.

**ANAGLYPHS.—RELIEF** says: "In your issue of June 2 appeared a paragraph with reference to the anaglyph. I have for many years been greatly interested in stereoscopic photography, in which, of course, there is no patent or exclusive rights of production. I beg to ask whether you could, and would, kindly inform me whether there can be any exclusive right to produce views for the anaglyph, and to make the glasses? I am induced to put these queries to you by the last three sentences in your notice, particularly the last sentence, in which you remark, 'It is a pity more attention is not devoted to it in this country.'"—In reply: In our opinion, the production of anaglyphs and the glasses is open to any one.

**PAINTING BACKGROUNDS.—BACKGROUNDS** asks: "1. What materials are necessary for painting photographic backgrounds on brown paper, and where purchased? 2. Whether any knowledge besides drawing is required?"—1. Ordinary distemper colour. Size, whiting, lampblack, or other pigments. The distemper should be mixed warm, then allowed to become cold, and applied in the j-lled state. 2. Nothing beyond a little experience in laying on the distemper, which is easily acquired.

**CRACKED NEGATIVE.—P. R.** asks: "Could you oblige by telling me how to strip off film from the broken glass? The film is not broken at all. I cannot copy it because it cracked before I could get a print off, and cannot get them to set again."—First alum the negatives or treat it with formalin, wash, and then immerse in a diluted hydrofluoric acid—five or six minims per ounce of water. In a short time the film will leave the glass, and may then be washed in two or three changes of water. Have ready a glass plate that has been coated with a weak solution of gelatine and allowed to set, then float the film upon it, remove, and rear up to dry. It is needless to say that air bubbles must be avoided in the operation.

**COPYRIGHT.—H. C.** says: "Kindly permit me to put the following questions with reference to copyright. 1. Is it legal to copy photographs, which do not bear the mark 'copyright,' according to the old Copyright Act? 2. Would the new Act, if it comes into operation, prevent me from executing any orders for copies without the permission of the authors of the photographs? 3. Would the amendments of the new Act have a detrimental effect on firms whose style of business lies mainly in the production of black-and-whites and coloured enlargements, either from direct negatives or copies?"—In reply: 1. It is not legal. If the copyright is registered, the copyist runs the risk of an action. 2. Yes; but the new Act is not likely to come into force—at any rate this session. 3. The amendments would very seriously interfere with such a business.

**COPYRIGHT.—JOHN WICKENS** says: "A brother professional took a photograph of the late Tom Ellis, and only parted with three prints. No charge was made for the sitting, and about a week ago my friend found that the photograph had been reproduced by a firm of jam-manufacturers. Immediately after Mr. Ellis's death the negative was registered at the Stationers' Hall. The three prints were then out, and my friend can trace them all, but none of his had gone to the firm mentioned. He made a complaint to them, but they denied all liability, stating that the print they used was not stamped with the word 'registered,' or 'copyright.' Now, what I want you to answer is the two following questions: 1. If, by any chance, this firm should have secured a print prior to registration, is there any claim, bearing in mind there was nothing paid for the sitting? 2. Is it absolutely necessary to have the word copyright on the print when registration is effected?"—In reply: 1. In our opinion penalties and damages could be recovered. We advise you to make a claim. 2. No. The Act (you will find it in the ALMANAC for 1899) imposes no such rule or regulation. The firm of jam-manufacturers deserves to be smartly punished.

**A NOTICE TO QUIT.—CRIPPLE** asks: "1. Am I bound by the notice or answer to pay or get out? 2. Have I not a right to know who the new owner is? 3. If I cannot get out by the 29th, am I still bound by my agreement to stay until March? 4. Am I bound to pay the rent to the old landlord? You see, the man I rented the house of this last seven years has sold it, and I pay him the rent the same; the lady owner don't want to be known, but wants to get 2l. 10s. per year more. The one that sold it is acting for her, you will see by the notice: 'Notice.—I am requested by the owner of S. L. S. R. (which you now occupy) to inform you, and hereby please take notice, that after September 29, 1899, the rent of S. L. will be 22l. 10s. per year, payable upon the usual quarter days. If you do not agree to this, please let me know by giving notice as per agreement, viz., three months from the 24th inst. Should you not do so, I shall take it that you agree to pay the advanced rent.' 'Reply.—You may inform the lady owner of S. L. that I refuse to pay the advanced rent and accept her notice.'"—In reply: 1. It seems to us that by formally accepting the notice you must leave on September 29. 2. We think not, if the notice is given by the owner's solicitor, duly accredited. 3. By accepting the notice you will have to leave September 29. 4. Pay the rent to the one who let the premises to you, unless he gives you authority to pay it to some one else.

**STUDIO PHOTOGRAPHY.—DUFFER** says: "It is my intention to shortly open a studio in a small way, but wish to turn out high-class work. I shall be very grateful, therefore, if you will answer the following queries: 1. What kind of plate is most suitable, and whose make would you recommend? 2. What kind of paper is it that first-class photographers use that tones so beautifully? Where can I get it, and can you say the process adopted? 3. Is it imperative, to secure the very best results, to use a portrait lens, or will an R.R. by good maker be equally suitable? 4. Where can I get good mounts from in small quantities? 5. If requested, may I copy portraits for any one, mounting the copies on mounts bearing my name?"—In reply: 1, 2, 4. Consult our advertisement columns, as it is quite against our rule to recommend any particular manufacturer's goods. 3. No, only that portrait combinations are much quicker in action. 5. You may, of course, copy other people's work if it is not copyright. Whether you mount them on cards bearing your own name is a matter of taste. But, if you do so, representing that it is your own work, it would decidedly be immoral. We cannot help thinking that our correspondent's *nom-de-plume* is not ill-chosen if he thinks to start a high-class business, even in a small way, with the limited knowledge of photography he seems to possess. We should advise him to article himself to a first-class photographer for one or two years before attempting a high-class business.

## EX CATHEDRÂ.

THERE are parts of Mr. Crooke's Presidential Address to the members of this week's Gloucester meeting of the Photographic Convention of the United Kingdom which deserve to be pondered by all classes of photographers; but we imagine that his professional brethren who have not had the advantage of listening to the address will turn with more curiosity and interest than any other class to the printed words in search of anything Mr. Crooke may have said that bears upon the position and future prospects of professional photography and its most important branch—portraiture. The foremost position Mr. Crooke has won for himself in the ranks of modern photographers invests anything he may say on this subject with the weight and respect which authority always commands, while the thoughtful and deliberative temperament conjoined to a high degree of artistic and æsthetic cultivation of which he is known to be the possessor add increased importance to the views which he lays before his fellow-photographers.

\* \* \*

THREE points stand out with the utmost clearness from Mr. Crooke's address. While, on the one hand, he does not ex-

pressly say that he foresees a declining future for portrait work of the commercial and show-case kind, on the other he is sanguine that for pictorial portraiture the public field is an ever-widening one. He tells us—and nobody in Great Britain should know better whether this is, or is not, so—that there is at present a marked appreciation of high-class pictorial portraiture, and that the men who produce it will be sought after. This is an observation which we ourselves have often made and commented upon, and we are pleased to find confirmation of it at Mr. Crooke's hands. The future hopes of pictorial portraiture rest on the efforts of such men as Crooke, Barnett, Baker, Hollyer, to bring home to the public the flexibility of photographic portraiture in responding to the touch of the photographer's own temperament and individuality on the one side, and of extracting from the sitter, on the other side, the many subtle shades of character which go to make up a personality. The "usual thing," to quote Mr. Robinson's classic phrase, will, doubtless, long hold a place in photographic productions, but it is to the higher or pictorial aspects of portraiture that we must look in the future for the salvation of a branch of the profession over which the tears of lamentation fall without ceasing.

\* \* \*

MR. CROOKE gives all photographers, no matter what class of work they produce, a practical hint of no inconsiderable value. He tells them to set their houses in order in the literal sense. So long as the photographer conducts his business after the style of the little tradesman, so long will the public rate him and his productions at no higher level than that upon which the wares and business methods of the grocer or the bootmaker may be placed. If at some of the more pretentious establishments there is far too much vulgar and gilded display, calculated to repel rather than to attract the patronage of cultured people, it is no less true that thousands of photographers' businesses all over the country are conducted in dingy shops and in loftily situated rooms, approached by narrow passages and staircases, which, in these days of increasing luxury and refinement of even commercial surroundings, demand a great deal of courage and self-sacrifice on the part of sitters, particularly ladies, to accept or to accustom themselves to. Mr. Crooke boldly says that the shop should be abolished, and that your earnest, artistic, or pictorial

photographer should practise his profession as other professional men do, in private-house surroundings. Among the foremost men in the profession this is done to some extent even now. While, however, we can scarcely look for a wholesale adoption of the idea amongst the rank and file of photographers, we yet perceive that, if the large majority of them would instal themselves in establishments which, in taste, style, and *mise-en-scène*, rejected the mean and often squalid appearances of the side shop and the dark passage decorated with forbidding specimens of inferior work, the public, instead of severely refraining from patronising photographers' studios, would, unquestionably, be attracted to them in rapidly increasing numbers. In the conduct and management of even a middle-class photographic business there is unlimited scope for the display of good taste in decorations, appointments, and furniture, and Mr. Crooke deserves well of his brethren for emphasising the point in the way he has done.

\* \* \*

A RECENT number of the *Journal of the Society of Arts* announces that the Albert Medal for the present year has been awarded by the President and Council to Sir William Crookes, F.R.S., for his extensive and laborious researches in chemistry and in physics; researches which have, in many instances, developed into useful practical applications in the arts and manufactures. Sir William Crookes was among the first to employ the spectroscope as an instrument of chemical research, and by its aid, in 1861, he discovered the metal thallium, the earliest of the series of the "rare metals." To his researches was also due the discovery of the various earths now so extensively employed in obtaining a large increase of light from illuminants. In 1872 he began the long series of experiments on radiation, of which the radiometer was the first outcome. This work on molecular physics in high vacua led to methods of producing extremely high vacua, which made possible the construction of the incandescent lamp. They also enabled the remarkable properties of the cathode rays (which are affording such important results in connexion with surgery) to be discovered and developed. He has rendered important services to industrial chemistry, and long ago established a position as an authority on the chemistry of dyeing and calico printing. His work in connexion with the chemistry of agriculture also requires to be noted. His services to pure science have been acknowledged by the award of a Royal medal, and of the Davy medal of the Royal Society; and it is the application of these researches to industrial uses which led the Council of the Society to submit his name to the President for the award of the Albert Medal.

\* \* \*

At the Convention this week Mr. Ward, of Messrs. Wellington & Ward, showed us a number of negatives on the new dry stripping film which his firm are shortly introducing. When the negative on its paper support has been removed from the ferrotype plate upon which, after development, it has been squeezeed, the point of a sharp-bladed knife is run along one of the shorter sides of the film. Sufficient pressure is applied to the knife to enable it to penetrate the film only, without cutting the paper beneath. The point of the knife is then introduced under the film to free the edges to the depth of about half an inch. This having been done, the corner of the film is taken between the fingers, and it can then be readily peeled from the paper support. The whole thing is accom-

plished, with a very little practice, in a few seconds. It can easily be seen that such a system of making pellicular negatives has very great advantages to recommend it to photographers.

\* \* \*

WE were sorry to learn, on Monday last, that on his arrival at Gloucester Mr. R. Child Bayley, editor of *Photography*, met with an accident by a fall from his bicycle. The result was a breakage of the leg above the ankle, necessitating Mr. Bayley's instant removal to the infirmary, of which he is likely to be an inmate for a week or two. The accident occurred within a few yards of headquarters. We are sure that our readers will join us in an expression of sympathy with Mr. Bayley in this peculiarly distressing accident, occurring as it did on the opening day of the Convocation, in which he was down to take a prominent part. We sincerely wish him a speedy recovery.

\* \* \*

THE latest, and certainly an original, form of photographic piracy has been brought to our notice by Sir Henry Trueman Wood. It was discovered in operation in the meeting room of the Society of Arts a few nights ago. It appears that on the occasion of a lecture, which was illustrated by lantern slides of a diagrammatic character, Mr. George Davenport, the well-known lantern expert, who is responsible for the working of the very fine projection system at the Society, heard the click of a shutter release proceeding from the auditorium. Inquiry revealed the fact that a gentleman who had come for the purpose of hearing an important illustrated lecture on a scientific subject had provided himself with a hand camera, with which, by means of time exposures (the instrument, of course, being supported to allow of several seconds being given), he was photographing the diagrams that were being shown on the screen.

\* \* \*

UPON being requested to do so, he stopped taking these "photographs in the dark." Sir Henry Wood tells us that he was not present at the time, otherwise the photographer in question would not have got off so easily. In the case under notice, it is to be presumed that the motive actuating the surreptitious photographing of the lantern picture was the desire to obtain copies of a set of engineers' drawings before they were published. We have considerable contempt for the vulgar pirate who copies photographs or pictures in which he holds no rights, but a great deal more for the man who can allow himself to commit the offence of making the occasion of a scientific lecture the opportunity of directing a hand camera to the use of appropriating a lecturer's original drawings. Possibly this description of the newest form of photographic piracy may put lantern lecturers on their guard against allowing valuable pictures to remain on the screen long enough to be copied.

#### SHELLAC IN PHOTOGRAPHIC TECHNIQS.

FOR some reason unexplained, if, indeed, explainable, this substance, one of most extensive employment in the arts generally, and in photography in particular, is the subject of such misrepresentation, such erroneous description, such misleading instructions, as almost to approach the mysterious. Let us, for example, turn to that monumental example of patience, industry, and, usually, of scientific precision, *Watt's Dictionary of Chemistry*, under the heading of "lac" (incidentally we

may observe that the word lac itself has a specific application to the dye-stuff, while the resin is commonly known with a qualifying addition—thus, shellac, stick lac, seed lac, button lac, white lac, the former, again, being described, according to its colour, as orange lac, garnet lac, &c.).

We read, referring to stick lac: "These twigs are called stick lac. The lac is removed by melting and squeezing through canvas, when the hardened drops are known as seed lac. After bleaching by chlorine or charcoal, and making into sticks, it is known as shell-lac or shellac." As a matter of fact, shellac means lac in the form of shells or scales, not sticks; it does not require to be bleached to earn the name; it is not bleached by charcoal; seed lac is not the melted drops of lac exuded from the canvas. This, it will be admitted, is a fair crop of errors to be found in half a dozen lines of scientific description; but that work is by no means the only one that sins in this connexion. One of the cherished fables of photographic recipes is, that if we dissolve shellac in spirit, and shake it up with charcoal, it becomes decolourised. We can only say that we have tried the plan with many samples of shellac, using both vegetable charcoal and freshly burned animal charcoal, and the result has been just the same as if we had read a page of Bradshaw to it. Again, we are told in many places that, if we expose it to sunlight, decolourisation takes place. We have placed narrow phials full of varnish, for six months, in a window with a south light, and we have been unable to detect the slightest alteration of colour. Possibly, if we had employed a spectroscope, we might have detected a change, but the colour of a varnish is not usually tested in that manner for commercial purposes.

Dealing now with the practical aspects of our subject, we meet at the outset one particular disadvantage in the manufacture of shellac varnish, the staple basis of all the best photographic varnishes; we refer to the great wastefulness that cannot be avoided when the lac is dissolved in methylated spirit. A very large volume of the liquid becomes useless, owing to the presence of a flocculent precipitate that never dissolves, and, even after months of standing, will not settle into a small bulk, and, moreover, will not satisfactorily filter out. It soon clogs a filter, and, consequently, very little of the thick part of the varnish can be saved that way. This thickened liquid may, however, be used with advantage, with a further quantity of shellac added, as a varnish for woodwork—printing frames, dishes for holding liquids, and so on. It has often been stated that the liquid can be cleared and the precipitate compacted by adding such substances as plaster of Paris, &c. We may say that our own experience has been quite unsatisfactory with all or any of these methods. We consider there is most promise in a suggestion of Mr. Watmough Webster, that the precipitate might be reduced in bulk by placing the crude lac solution in a centrifugal machine.

Ordinary white lac is especially liable to this waste; but the fresher the lac the smaller the waste. If used when too old, we have seen the solution remain without any perceptible clearing for months after the soluble portion has been taken up.

Aqueous solutions of shellac subserve a variety of uses, they are used for varnishing negatives by simple immersion while the film is still wet; when put up to dry and drain, they dry as soon as under ordinary conditions and are then ready-varnished. Aqueous lac solution has been used for rendering paper impervious to water for the autotype process, but it has the defect of becoming discoloured by age. The

modes of making aqueous solutions are many and various. The plan adopted in some trades, the hatter's for instance, of dissolving in a boiling solution of borax, is not suitable for photographic purposes. When small quantities only are needed, the best plan is to add a few drops of strong ammonia solution to, say, an ounce of varnish, the varnish so treated will mix with water in any proportion without precipitation. When required in quantity, the shellac may be soaked for some time in a solution of carbonate of soda or carbonate of ammonia, it is then soluble in boiling water. For a useful, strong, hard light-coloured varnish, a mixture of two parts of best orange shellac and one of fresh white lac makes a varnish difficult to surpass. The addition of gum sandarac or benzoin is often recommended; the addition heightens the brilliant glossiness of the surface, but renders the varnish less tough and less able to resist ordinary wear and tear.

There is still room for the publication of a really good method of making shellac varnish, or a way of treating shellac that will render it soluble, or at any rate do away with waste in its making. As an aid in experimenting, it may be useful to know the chemical composition of lac, and we will conclude our remarks by quoting from a paper by Herren Schirch and Farmer, which gives it as follows: Wax, 6; colouring matter, 6.5; purified resin, 74.5 (of which sixty-five per cent. is soluble, the remainder insoluble in ether); residue, 9; and water, &c., 3.5 per cent.

---

**Photography as a Profession.**—On several occasions when alluding to the over-stocked photographic labour market and the small salaries paid, we have mentioned that any trade or calling which is easily acquired is sure to have a superabundance of labourers. So it is with photography. Some very strange ideas prevail with regard to the knowledge necessary to commence professional photography, but nothing stranger has come under our notice than the queries put by a correspondent, and replied to last week. He says he wishes to start a *high-class* business in a small way (the italics are his). He then asks what plates to use, what paper, and how to produce the same beautiful tones that professionals get, where to buy mounts, whether a rapid rectilinear lens is as good as a portrait one, &c. Most of our readers will be amused that any one should entertain the notion of starting a business—let alone a high-class one—who has to put such questions as the above to us. The *nom-de-plume* he has selected for the answer to appear under, some will think was not ill-chosen by one who thinks of commencing a business with such a limited knowledge of its requirements.

---

**Persecuted by Photography.**—The ubiquitous photographer seems to be as prevalent and as persistent in France as he is in England. We are told by the special correspondent of the *Standard* that Madame Dreyfus and her relatives are being much persecuted by photographers, who endeavour to catch her in every possible position as she passes to and from the prison at Rennes, where her unfortunate husband is at present confined. The correspondent, in writing, says that, the day before, an enterprising firm had installed a cinematograph apparatus in the vicinity of the prison to take pictures of the lady's departure, and adds, M. Havel, endeavoured to protect her from this annoyance, and the films were probably spoilt. Let us hope they were. To be snap-shotted against one's will by hand cameras is bad enough, but being cinematographed is infinitely worse. Hand-camera pictures, as a rule, are principally confined to private collections. Not so, however, with cinematographs, they are taken for exhibition at places of public entertainment. Madame Dreyfus has our sympathy.

**The Dismal Photograph.**—Mr. Lethaby, Inspector of Technical Instruction and Art Classes under the London County Council, is evidently no great admirer of photography; for, in a paper read last week before the Women's International Congress on the "Special Aptitude of Women for Handicrafts," he is reported to have said with regard to drawing: "Then the portrait. It is absurd that, with such a host trained as painters, there should be no practical mean between the 100 and 1000 guinea oil and the dismal photograph." He then proceeds to ask, "Why might not some girl who could draw do a two hours' portrait in pencil for a guinea?" At this there was applause. So far as we can see, there is no reason why she should not, for the work would certainly be remunerative, if—and there is the "if"—she could get commissions for them. At present, we suspect that the public will prefer a dozen or more "dismal photographs" for their guinea than one two hours' pencil portrait. However, art training amongst girls should be encouraged, though it may be unwise to hold out hopes to the students that are not likely to be realised.

**Royal Arms Prosecutions.**—Some photographers who use the Royal Arms on their show-cases, bill-heads, circulars, &c., do not appear to be aware that they are breaking the law and subjecting themselves to heavy penalties. On Tuesday, last week, a hatter, in the Strand, was proceeded against at Bow-street Police Court for using the Royal Arms without holding the Royal Warrant entitling him to do so. He was mulcted in a penalty of ten pounds and three guineas costs. Two others were also fined smaller amounts for similar offences, and on Tuesday an undertaker in the Euston-road was prosecuted, at the Clerkenwell Police Court, for a like offence. For this defendant it was pleaded that he thought he had the right to use the Royal Arms as they had been exhibited over his premises for forty years. In this case the magistrate inflicted a fine of ten pounds with three guineas costs. The magistrate remarked, during the hearing of the case, that the maximum penalty was fifty pounds. It is a very common idea that, if any one supplies anything to the Queen or others of the Royal Family, they are forthwith entitled to use the Royal Arms, and they have done so. It is a fallacy, however, and is an offence against the law. To use the Royal Arms, a warrant to do so must first be obtained. We call attention to this subject, because we suspect that some are ignorant of the fact that supplying photographs to members of the Royal Family, or to the Queen herself, does not entitle them to use the Royal Arms or any colourable imitation thereof.

**The Decoration of the Royal Exchange.**—One day last week another of the mural paintings that are to embellish the Royal Exchange was unveiled, the ceremony being performed by the wife of the Master of the Mercers' Company. The painting is by Mr. Ernest Crofts, and represents the opening of the building in 1571 by Queen Elizabeth. This picture is a valuable addition to the historic gallery which is gradually filling the panels of the Royal Exchange. When all are finished, the Exchange will possess one of the finest galleries of historical pictures, by modern artists, in this country. Of course, all the pictures are painted according to the imaginations of the artists, assisted by such paintings and drawings of the periods that are available—and they are not many. Probably, had photography been in existence in 1571, it would have depicted the opening ceremony by Queen Elizabeth somewhat differently from that represented by Mr. Crofts, though it is doubtful if it would have been better pictorially.

**Antarctic Exploration.**—Some little time back we mentioned that the Royal Society, together with the Royal Geographical Society, had approached the Government with regard to assistance in fitting out an expedition to explore the Antarctic regions. At that time the Government did not see its way clear, though sympathising with the object, to give the desired assistance. However, the Lords of the Treasury, in a letter last week to Lord Lister, the President of the Royal Society, say that they are prepared to ask Parliament for grants amounting to 45,000*l.* towards the expenses

provided the Royal Society and the other promoters are able to assure a like sum so as to enable the scheme to be efficiently carried out. Although the northern regions have for many years past received much attention, the southern have been almost entirely neglected. Now there is a prospect that there will be an expedition to the Antarctic regions, and it is needless to say, that photography will take an important place in it.

## PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

GLOUCESTER MEETING, JULY 10-15.

For the fifth time in its history the Photographic Convention of the United Kingdom meets in a western city, Bath, Chester, Shrewsbury, Plymouth having been the scenes of former gatherings. It would seem from this that the members have a preference for holding the Convention meetings at places having the quiet characteristics of a cathedral town. Experience has shown that in large cities like London and Glasgow there is a lack of cohesion amongst the members during the Convention week. The "magnificent distances" that separate the various points about which Convention interests centre during the week not only keep the members a great deal apart but over-fatigue them, and thus rob them of the opportunity of doing the fullest justice to the programme provided.

But in a town like Gloucester, with its forty odd thousand inhabitants, only and its one dominating attraction of the cathedral, past the very doors of which the human tide daily ebbs and flows in the very centre of the town, a trumpet call might easily bring all the members together.

The Guildhall, the official meeting-place, is perhaps one minute's walk from headquarters, which, in its turn, is no more than a stone's throw from the other hotels and private houses at which members have been staying during the week. Thus the feeling of being quartered near to one another is a valuable factor of estimating the amount of success which may be expected at any particular meeting of the Convention.

Upon the architectural and archaeological attractions of Gloucester as a photographic rendezvous it is needless for us to dwell; this was done with admirable point and detail by Mr. Medland in the official guide-book. Rather let us say that, by historical interest and picturesque surroundings, no more agreeable scene for the Convention meetings could have been chosen than this placid western city.

It is the fourteenth annual meeting of the Convention. The hand of illness and other causes have kept such old supporters as John Stuart and A. L. Henderson away from the busy scene of photographic talk and work; but, in the persons of Mr. George Mason, of Glasgow and Mr. Alexander Tate, of Belfast, the link with the past remains unbroken, and the continuity of Convention traditions has been maintained. We should be extremely sorry to see the Convention robbed of that tradition. It gives opportunity once a year for all sorts and conditions of photographers to meet on the common level of devotion to a fascinating branch of "fine art," as the Act of 1862 graciously permits photography to be termed.

The scientific, practical, artistic, commercial, professional, and amateur aspects of photography are the subjects upon which ideas are freely exchanged during the week, and we can speak from personal observation when we say that a Convention meeting forms a radiating point whence photographic knowledge is transmitted to many points, near and far.

One of the great charms of the Convention is the opportunity it gives for the display of good fellowship. It is informal; it is conducted by photographers, for photographers, and without the outside assistance of social or aristocratic favour. There are some persons who would like to see this annual gathering of photographers turned into a "function" which it would be the "correct thing" for local society to patronise and "do." We gravely doubt whether, on the one hand, photographers would tolerate being taken by the hand in this manner, or, on the other, whether county magnates and aristocrats could be induced to feel sufficient interest in the proceedings of a peripatetic institution which in the nature of things cannot be expected to take rank with the British Association and other gatherings of the kind to which the intellect of the world annually turns.

Fine weather ushered in the week, and the old familiar scene again presented itself to us: the gathering on the Monday morning of troops of members, who had not met since last year at Glasgow. Many old faces, as we have hinted, were missing, but each meeting of the Convention always sees a batch of new members to take the place of those who are compelled to be absent.

## THE EXHIBITION.

The feature to which Convention visitors turn at the earliest moment is the usual exhibition of apparatus and photographs. It is held this year in the large hall of the Guildhall an apartment eighty feet by forty feet. It cannot be said that the pictorial part of the exhibition compares favourably with the displays given at Glasgow, Great Yarmouth, and Leeds. Indeed, but for the efforts of the Platinotype Company, there would have been little of the highest class of work to be seen. This Company sends about forty reproductions of well-known pictures in platinum. They are framed in plain, flat wooden frames coated with a grey pigment of a light tint, and are hung on dark green cloth under the gallery. The lighting is unavoidably imperfect, but the selection of pictures gives the visitor a good idea of the capabilities of this process for translating paintings into monochrome.

Kodak, Limited, occupy nearly the whole of one wall space with a large stand, whereon one sees set forth examples of all the productions of the Company in the way of apparatus and printing papers. Messrs. W. Watson & Sons, of 313, High Holborn, are represented by a typical selection of the apparatus they manufacture, prominent on the stall being the Acme camera, the new binocular stereoscopic camera, and the Ives Kromskop, which attracts the delighted attention of visitors. Messrs. Wallis Brothers, of Kettering, show their roller-blind shutter. The Tella Camera Company occupy a stand. By the aid of a glass-sided camera Mr. W. E. Dunmore, the Managing Director of the Company, illustrates, for the enlightenment of visitors, the ingenious mechanism of one of the most novel and beautiful hand cameras that have recently been introduced. Messrs. Burroughs, Wellcome, & Co., send a large glass-covered case filled with tabloids of their manufacture for photographic use. Lenses and cameras are shown by Messrs. Ross, Limited. The principal movements of the Sanderson camera have been applied to a hand camera, and this, among other apparatus, was demonstrated at Messrs. George Houghton & Sons' stall by Mr. Sanderson, the inventor. Secco film was demonstrated by Mr. J. H. Avery. A series of prints from negatives by Mr. Sandell, contributed by the Sandell Plates and Film Company, illustrate the capabilities of those plates for producing results free from halation, &c. Cinematographic apparatus formed Mr. R. W. Paul's exhibit, and the Velox papers also figured on one of the stalls, Messrs. Griffin having arranged for the paper to be practically demonstrated. Mr. H. Snowden Ward sent a collection of colour prints which are hung on the wall spaces surrounding the platform.

Local work is represented by a numerous exhibit from the Gloucestershire Photographic Society. The architectural work of Mr. W. C. Beetham and Mr. H. B. Milner is of special excellence, and among the exhibits there are some very good landscape studies. Among local professionals, Mr. H. W. Watson and Mr. E. Debenham send pleasing examples of work, the latter gentleman contributing an enlarged portrait of his well-known brother, "W. E." of that ilk.

On the whole, visitors find a great deal in the Exhibition to interest them, our references showing that many of the latest productions in photography were placed on view for their inspection.

## THE EXECUTIVE.

The Executive Committee of the Convention consisted of Messrs. H. Medland (Chairman), Oscar C. Clark, M.B., H. S. Crump, R. W. Dugdale (Local Hon. Secretary), W. Hodges, L.R.C.P.

The Local Committee was as follows:—Dr. Campbell, Messrs. James Clarke, Oscar Clark, Rev. Travers Clark, Messrs. J. H. Collett, J. M. Collett, H. S. Crump, C. H. Dancey, F. Fielding, J. Hole, E. A. Ind, S. G. Jones, H. Knowles, E. Lea, E. Mansfield, H. G. Madan, H. Medland, E. J. Neinenger, A. H. Pitcher, Herbert Sessions, A. Simpson, A. Slater, J. Tibbitts, F. A. Trotman, W. E. Vinson, Dr. Watters, Messrs. T. H. Washbourne, H. W. Watson, Geo. Whitcombe, W. B. Wood, G. Embrey, and W. Walwin.

Bath Photographic Society.—Surgeon Major Adcock, M.D., and Mr. G. F. Powell.

Herefordshire Photographic Society.—Messrs. Gus Edwards and Cecil Gethen.

The Hon. Local Secretary was Mr. R. W. Dugdale, 25, Kingsholm-road, Gloucester, and the latter gentleman, with Mr. Crump and Mr. F. A. Bridge, the General Hon. Secretary, were most assiduous in attending to the wants of visitors to the Convention—no light task, when it is considered what a multitude of detail work has to be taken in hand during the week.

On Monday afternoon a party of between sixty and seventy undertook the excursion, by brake, to Elmore, Fretherne, and Frampton-on-Severn.

The weather was inclined to be showery. The Cathedral, the picturesque old inns, and some other architectural antiquities of the city also supplied many opportunities for photographic work.

## THE CONVERSAZIONE.

On Monday evening the *Conversazione* was held in the Guildhall, the members being received by the Mayor, the City High Sheriff, and the Corporation of Gloucester. Music was provided, and refreshments were served during an interval in the proceedings. In our experiences of Convention *conversazioni* we have not seen a larger or more representative gathering of members. In addition to the civic party, which appeared in full state, many of the most prominent citizens of Gloucester attended the ceremony, and the scene in the roomy Guildhall was an animated and brilliant one throughout the evening.

In some quarters recently there appears to have been promulgated a fantastic notion that the absence of some half-dozen gentlemen from this year's Convention would be fatal to its success as a numerous and representative gathering. The best, and indeed the only, answer called for by the amusing lamentations in question, is a list of a few of those present at Monday evening's function, which we here append:—

The Mayor and Mayoress of Gloucester, the City High Sheriff, the Town Clerk, the Mayor of Cheltenham, Mr. William Crooke (President), Mr. H. P. Robinson and Mrs. Robinson, Mr. and Mrs. George Mason, Mr. C. H. Bothamley, Mr. F. A. Bridge, Mr. R. H. Dugdale, Dr. Hodges, Mr. and Mrs. Snowden Ward, Mr. E. J. Wall, Mr. Thomas Bedding, Mr. A. Horsley Hinton, Mr. A. Lindsay Miller, Mr. Godfrey Bingley, Mr. Harold Baker, Mr. J. W. Furniss, Mr. Allen Nield, Mr. C. Phipps Lucas, Mr. E. J. Humphery, Mr. H. Vivian Hyde, Mr. William Taylor, Mr. C. G. Emery, Mr. H. Walter Barnett, Mr. T. C. Turner, Mr. Frank Turner, Mr. W. E. Dunmore, Mr. G. M. and Mrs. Bishop, Mr. F. W. Hindley, Mr. Hirst, Mr. E. Peake, Mr. J. T. Sandell, Mr. and Mrs. A. Priestley, Mr. W. H. Smith, Mr. W. J. Croall, Mr. G. Fowler Jones, Mr. and Mrs. De'Ath, Dr. and Mrs. Adcock, Mr. H. R. Milner, Rev. E. T. Clark, Mr. F. H. Burr, Mr. G. W. Watson, Mr. S. H. Fry, Rev. T. and Mrs. Perkins, Mr. W. M. Harrison, Mr. W. D. Welford, Professor Stebbing (Paris), Mr. Alfred Watkins, Mr. B. W. Robinson, Mr. A. Clout, Mr. E. J. Appleby, Mr. S. B. Webber, Mr. J. L. Lyell, Mr. E. Debenham, Mr. Washington Teasdale, Mr. Charles Winter, Mr. T. A. Scotton, Mr. J. M. Dickinson, Mr. J. Lawley, Mr. Wilfred Emery, Mr. W. W. Nauntou, Captain Adair, Major Lysaght, Mr. G. Watmough Webster, and some three hundred other ladies and gentlemen whose names it was impossible to obtain.

The Mayor, having taken the chair, extended a cordial welcome to the Convention, remarking that Gloucester was always pleased to welcome such bodies. No branch of art had made such progress in recent years as photography. He wished the members of the Convention fine weather to enjoy the scenery of what he considered to be the most beautiful county in England.

Mr. C. H. Bothamley moved a vote of thanks to the Mayor and Corporation of Gloucester for their welcome, expressing regret at the unavoidable absence of the retiring President, Mr. John Stuart, through illness, he introduced the new President (Mr. William Crooke), of whom the speaker remarked that his admirable work had made his name known wherever photography was practised. Mr. Crooke did not talk or write about "art," but did it.

The President then took the chair, amidst loud applause, and read his opening address.

## PRESIDENT'S ADDRESS.

In opening this, the fourteenth meeting of the Photographic Convention of the United Kingdom, I might call your attention to a statement, contained in the useful little pamphlet issued prior to the Convention, that the first meeting was held in Derby in 1886. The number attending on that occasion is frankly stated as forty-six. It must be very gratifying to the originators of this reunion of photographers (many of whom are in our midst to-night) to watch its steady growth from year to year, showing how the facilities afforded by it for interchange of ideas and cultivation of lasting friendships are appreciated. In the increasing number who take advantage of the opportunity for a shake of the hand, we see evidence of the *bonne camaraderie* existing among the brethren of the black art. I can vouch from personal experience for the pleasant memories left by the Convention week on many previous occasions.

## COPYRIGHT.

Let me at once touch on one or two matters which I know are sure to be uppermost in your minds as photographers. Since the last meeting of this Convention, as most of you are aware, a Copyright Bill has been

brought before the House of Lords by Lord Monkswell. This Bill demands particular attention, as it is a measure which directly affects the interests of all photographers, amateur as well as professional. The existing Act of 1862 has been found to work very satisfactorily, and it is impossible to discover any reason for seeking to alter or modify it. However, our friends, the artists, for some not very obvious reason, are asking Parliament to deny photography the legislative rank and privileges of a fine art. They want to reduce the term of photographic copyright to thirty years, make registration compulsory, and render impossible the continuance of the present amicable relations between photography and the illustrated press. There is not the slightest chance of the Bill passing into law this session, but it is satisfactory to know that the Copyright Union and the Royal Photographic Society have been instrumental in placing before the Select Committee of the House of Lords the grave injustice proposed to be done to copyright in photography. It is probable that these efforts will not be thrown away, and that, should the Bill be reintroduced next session, it will be considerably modified. But it behoves photographers to be watchful, lest an unmodified Bill should again be promoted by the artists, who are seeking to injure and degrade photography at a time when, compared with thirty-seven years ago, its pictorial, technical, and scientific excellences never stood higher. The proposed Bill would disturb an art and dislocate an industry, while it would not advantage the artist, so that we must assume some unreasoning jealousy to be at the bottom of the agitation.

#### THE PROTECTION OF THE PUBLIC.

While on the question of legislation I might venture to prophesy that some steps will be considered desirable, if not necessary, for the protection of the public from the ubiquitous snap-shotter. Some weeks ago a daily paper, in giving an account of the amateur golf championship, wound up with the remark that, "though cameras were plentiful, their manipulators were not so aggressive as on former occasions;" this hints at the followers of our art having a reputation for misbehaviour. One might sometimes attribute their eagerness to enthusiasm, but the laws of discipline and etiquette should not be ignored, the dignity of the profession ought to be upheld, and nothing should be registered calculated to give offence to any one. In fact, obey the golden rule, "Do unto others as you would have others do to you," and so stave off the evil day when your camera will be taxed, and yourself be adorned in the fashion of the street porter with your registered number on sleeve badge.

#### INDUSTRIAL PROGRESS.

Photography, as a scientific and artistic pursuit, has gained more followers than any other discovery of the age, and as a consequence the demand for apparatus and material has been very great, and we owe a debt of gratitude to the manufacturers for the zealous and conscientious manner in which they have looked after our every want. You will say with me that it is perfectly astounding, considering the vast quantity of plates and paper coated in the course of a year, what a small proportion of waste is caused by faulty manufacture compared with that of some years back. Every article being so reliable and uniform reduces our anxieties in respect to the technical part of our work to a minimum. It will be impossible for me in the time at our disposal to-night to give any idea of the progress made in photographic manufactures during the year, but I might mention that I have had the pleasure of using recently the Cadett & Neall spectrum plate. When used in conjunction with their light-filter the effect is charming, and will revolutionise landscape in the matter of tone values and colour luminosities. Of papers, platinotype still holds premier position; "Dekko" and "Velox" have proved a great boon, but up north with us carbon seems to be greatly in vogue. You may have heard of the boy who, being catechised as to why he was a Protestant, replied, "Because my father was one." Now I fear many photographers can give no better reason for the faith that is in them; they copy their neighbours and, though imitation is said to be the sincerest flattery, we experience disgust when a man's style is copied in its integrity, and amusement when copied in part, making the plagiarist's picture a thing of patchwork.

#### THE OLD AND THE NEW STYLES OF PORTRAITURE.

But, with all the facilities at our disposal, have we been utilising them for the furtherance of the art side of photography or "pictorial photography" as it is now called? On looking round our leading exhibitions, it is quite apparent to the most obtuse observer that the title "pictorial" applies more frequently to landscapes than to portraits.

A vast army of intelligent and artistic workers has brought its skill to bear upon the production of pictorial landscapes, and, being unfettered by

the tastes or fancies of others, the results of its labours that adorn our exhibitions are worthy in every sense of being styled "works of art."

Of portraiture I cannot speak so encouragingly, for the past few years it has almost been threatened with extinction from our pictorial exhibitions. If we go back to the shows at the beginning of the eighties, we find the commercial portrait occupying the lion's share of space; but gradually matters have changed, and now the Royal Photographic Society is inclined to think the commercial, or technically perfect, portrait should receive more consideration at its hands than of late years. I am not sure that this type of portrait needs such kindly consideration. The producers of it have enjoyed the biggest share of public patronage, and had a good laugh up their sleeve, at the expense of those struggling with pictorial work, while they amassed great fortunes. I am of the belief that a change is approaching which will render this step on the part of the Society unnecessary. The spread of photographic knowledge tinged with artistic taste is such, that only the work in which is embodied artistic treatment, combining the individuality of the subject with the mode of expression peculiar to the author, will ever make our exhibitions interesting and educational.

#### PICTORIAL PHOTOGRAPHY.

As one interested in pictorial photography, I feel my mission here would be unfulfilled did I not refer more particularly to this branch. Modern photography requires to be executed on entirely different lines to those of former days, but it is to be feared that too many, through inability or carelessness, keep on in the old groove, ignoring the spread of knowledge and enlightened judgment now brought to bear on the results of their labours, and finding consequently a decrease in number of commissions and difficulty in getting the fees they demand. With reference to one cause of failure, is it not due to the striving after effect, the inborn anxiety to make something out of nothing, which results often in making nothing out of what might have been something, for we must remember that our art has its limits, which, once passed, reveal its weakness? Let us rather endeavour to cultivate a taste for simplicity, repose, and dignity, depending little on those gorgeous accessories deemed indispensable by some.

I now address myself more directly to those who have, as it were, been standing by for years, looking on at the ordinary game played by the largest establishments in the world, and I hope to-night to instil into the hearts of these patient bystanders (who have been striving to bring about the desired advent) a lively belief in the assured future of pictorial portraiture. The germ of pictorial photography has not been dead all these years, but we must confess that it has been barely kept alive; the root, however, is still with us, and, granted a little nurture from a generous public, will spring forth into glorious life. There is a marked appreciation of high-class pictorial portraiture, and the men who can produce it will be sought after. The individual specialist himself must have so many qualifications that it is difficult to get them all combined in one individual, one being more successful with the gentler, another with the sterner sex, and yet another with children; in fact, a distinct aptitude for one of the three manifests itself. Be this as it may, portraiture should be a separate branch and the men who practise it artists; then the status of the photographer will rise, and the work that is devoid of artistic merit must in due course be assigned to the mechanical section at our exhibitions.

Might I crave the indulgence of those present who are not interested in this particular, while I presume to suggest what I consider the most suitable method of handling our environments at this turn of the tide? As a man is judged by the company he keeps, so may he also be judged by his surroundings. This impression starts at the very entrance door; if this is vulgar, you may look in vain for refinement within. If specimens of work be exhibited here, let quality, not quantity, be the motto, and this feeling should govern the whole establishment.

The present-day tendency is towards too much display, giving a commercial aspect which is not at all desirable or necessary, we want to see more of the æsthetic element asserting itself. My ideal photographer's "shop" is a private house with closed door. This, you argue, precludes our being heard of; but are we not privileged to affix our name to each individual effort? Not like my tailor who made this exquisitely fitting suit, and who is debarred from printing his name on the tails. You have your advertisement free of charge, and, there being always some congenial souls on the outlook for artistic work, they will find their way to your bell handle.

#### LENSES.

Here let me make a suggestion to opticians who have been at work so long calculating optically perfect lenses for the profession. One welcome

addition for portraitists would be a lens for studio work that would in some respects resemble the Berghem in diffusion of focus (too much focussing would be undesirable), but having sufficient depth to enable focussing to be done roughly, say, by measurement, in the studio, similar to that practised in outdoor snap-shooting. This would rectify the absurd method of making a focussing stock of your model. To talk of diffusion of focus is tantamount to waving the proverbial red rag. However, as a middleman, it is not inconsistent for me to wave it, as it might be on the part of some of my extremist brethren.

#### COLOUR PHOTOGRAPHY.

The progress of colour photography makes the most fascinating topic, especially when its wonders are explained in the public press. False reports, such as Mr. Muggins, Ecclefechan, has, after long and persistent labour, at last succeeded in giving to the world nature in all her various tints. This is the sort of thing we get from time to time. That progress is being made there is not the least doubt, but whether we shall derive all the pleasure we anticipate when it is *un fait accompli* is another question. I regret to express myself in this pessimistic manner, but individual taste is bound to assert itself disagreeably at times, and, if we can be vulgar in monochrome, our opportunities so to distinguish ourselves will be unlimited in colour. I shall leave the scientific aspect of this question to a more able exponent, my friend Mr. Child Bayley.

And now in my closing sentence let me echo Lord Charles Beresford when speaking of his book, *The Breaking up of China*, "I'm glad it's done; I'd rather fight a general action than write another book. You know I'm not a literary man."

At the conclusion of the President's address Mr. Alexander Tate moved a vote of thanks to Mr. Crooke, which, having been seconded, was warmly carried. On the proposition of Mr. F. A. Bridge (General Hon. Secretary), seconded by Mr. B. W. Dugdale (Local Hon. Secretary), a vote of thanks was passed to the Mayor and Corporation for all the trouble that had been taken to render the visit of the Convention a success. The hearty applause which greeted this proposition was an expression of the feeling, animating the whole of the Convention, that the civic authorities and local executive committee had spared no effort or trouble to make the visitors' stay a pleasant and happy one.

A delightful evening terminated with an exhibition of colour photographs, according to the methods of Ives, Lumière, Lippmann, and Joly. Mr. R. B. Beard and Mr. E. J. Wall worked the lantern, and Mr. H. Snowden Ward, in the regretted absence of Mr. Child Bayley (who is progressing favourably) described the pictures.

On Tuesday morning, in perfect weather, a very large party left for the excursion to Berkeley Castle. Owing to the fact that large numbers of members omitted to sign the attendance book, we are unable to give an idea of the numerical strength of the Gloucester Convention; but, at a guess, we should say that there must have been between 300 and 400 members present during the week, a larger proportion than usual being professional men.

At the Annual General Meeting, held on Wednesday morning, it was decided that the Convention should visit Newcastle-on-Tyne next year.

For the convenience of Convention visitors, Messrs. Marion & Co., of Soho-square, W., have arranged to have a large display of photographic apparatus and sundries, drawn from their unique stock, on view at the New Inn, where a large room is occupied for the purpose. The "show-room" is in charge of Mr. J. M. Dickinson, the able representative of the firm, and its contents ranged in variety and extent from a studio camera to a midget mount. It will be open to the inspection of visitors on Friday and Saturday, and is well worth a visit.

#### AMMONIUM PERSULPHATE.

The peculiarities of this substance continue to excite much interest in the foreign photographic press. In Dr. Liesegang's publication, *Der Amateur Photograph*, Hehlheim points out that various samples have been found to differ in their action, some behaving admirably, whilst others have no reducing power. Liesegang was the first to make known the reducing action of persulphate, and observed that old solutions were more active than fresh. Dr. Miethe confirmed this, and N. Schönchen has given the following explanation: Persulphate of ammonium tends to decompose when kept, and liberates a small quantity of free sulphuric acid. The latter causes the formation of ozone, and to this the action upon the silver forming the negative is due. It is therefore desirable to

add a few drops of sulphuric acid to the solution to ensure certainty in using the salt as a reducer. Riston, writing in the *Bulletin de la Société Lorraine*, pronounced the salt an admirable reducer for over-developed plates, but did not find it of use for removing the veil due to over-exposure. Namias recommended it for the removal of yellow stains, from whatever cause arising, and found it more effective than thiocarbamide. A one to two per cent. solution should be used, and, after the stain disappears, the negative should be immersed in a five per cent. solution of sodic sulphite and then washed. Miller has used the salt for making positives. After development of the negative the image is dissolved by immersion in a ten per cent. solution of persulphate. The plate is then washed, exposed to light, and developed as a positive. It is doubtful, however, if this process is superior to that based upon chromic acid.

Turning to the *Bulletin de la Société Française* for June 15, we find an interesting paper by M. A. Hélain on the Theory of Reduction by means of Persulphate of Ammonium. The writer holds that the theory propounded by MM. Lumière and Seyewetz is incorrect. The explanation offered by the latter was, that the reduction depended upon an oxidising and a solvent action of the persulphate upon silver and its salts. They held that these two actions did not counterbalance each other to the same degree upon the surface of the film and within it. The oxidising action to which reduction was due predominated to a certain depth of the film, but beyond, in that portion next the glass, the silver was dissolved and converted to a double salt. The following experiments were made by M. Hélain, and he holds that they are inconsistent with Lumière's theory:—

1. If two brief exposures are made, one direct and the other through the glass, when they are developed and treated with persulphate, it will be found that reduction takes place similarly in both. The second negative, although at the back of the film, does not lose more than the first in the process of reduction. In fact, the tendency is the other way.

2. If a negative is stripped, turned over, and transferred to another plate coated with gelatine, it will be found that the effect is the same when the plate is treated with persulphate. The densest portions of the film will be attacked, whilst the half-tones will remain unaffected.

M. Hélain is inclined to think that the process may bear some resemblance to that described by Captain Colson in his work, *La Plaque Photographique*, wherein he states that the gelatine parts with hydrogen in the process of development, and, in proportion to the opacities, undergoes a modification similar to that which an oxidising agent would produce. If persulphate is most pronounced in its action upon the densest portion of the negative; why should this not be due to the oxidised condition of the gelatine, which has thus become more or less insusceptible to the action of the reagent? In the transparent portions of the film, where there is more gelatine in an unoxidised condition, the persulphate of ammonium spends a portion of its energy upon the gelatine, and the silver suffers less.

#### PYROCATECHIN.

THE *Photographische Mittheilungen* again draws attention to this developer, which is closely related to hydroquinone. As it can now be manufactured chemically pure at a low price, and excellent formulæ for its use have been devised, it will probably take an important place amongst developers. It is often complained that fresh solutions of hydroquinone are prone to fog the plate. Pyrocatechin is free from this defect, and, whether fresh or several months old, yields negatives of great purity. Another advantage is that the image develops regularly and with rapidity. When the image has attained full strength, there is still some latitude, as it retains its character without risk of fog if the plate is left a little longer in the developer. This is more particularly the case with the pyrocatechin-phosphate formula (see THE BRITISH JOURNAL OF PHOTOGRAPHY, May 6, 1898, p. 296), and the pyrocatechin-caustic soda formula as follows:—

##### Solution I.

Sulphite of soda .....	25 grammes.
Distilled water .....	250 c. c.
Pyrocatechin .....	5 grammes.

##### Solution II.

Pure caustic soda .....	8 grammes.
Water .....	250 c. c.

For use take 1 part each of I. and II., and 2 to 6 parts of water.

If the formula for combined development and fixation is used (see THE

BRITISH JOURNAL OF PHOTOGRAPHY, May 19, 1899, p. 311), the characteristics of the plate and the exposure must be taken into consideration. Although there is some latitude even with the combined development and fixation formula, it is desirable to modify the formula for over or under-exposure. In the case of marked under-exposure it would be desirable to add more alkali to the developer, in order to obtain sufficient density.

### CYCLING WITH THE CAMERA.

It is the ambition of the amateur who has passed the elementary stage to take series of views of places of interest he may have visited during the holiday season—it may be his cycling tour—with the ultimate and laudable purpose in view of a lantern lecture—public or private, as the case may be—in the ensuing winter. Some such object as this is greatly to be commended, tending as it does to, at the least, some degree of proficiency in the technical details of negative and lantern-slide making, and bringing into play whatever he may possess of artistic selection and arrangement, without which, it must be admitted, the results would lose much of their value. The titles of such series are not generally called in question, except, maybe, by the hypercritical and hair-splitting onlooker. For instance, if I take a run on my “bike,” with camera *en croupe*, from Nottingham to Clovelly or Land’s End, taking *en route* Charnwood, Quorn, Leicester, Lutterworth, Rugby, Warwick, Stratford, Cheltenham, Gloucester, Bristol, thence (as I can particularly recommend) by steamer to Ilfracombe, on by road to Barnstaple and Bideford, and coach to Clovelly, it can scarcely be hoped for that we secure at the first attempt, and in the space of a limited holiday, *all* the interesting, not to say important, “bits” which will take the eye as we pedal swiftly from county to county. Apart from the failures attributable to a changeable climate, we have those which may be traced to—well, let us say at once our own fault and haste, and those which are distinctly the effect of faulty mechanical fitting of camera. Still, we can do a very great deal at the first time of asking in such a tour as this briefly referred to, weather being favourable.

Naturally one should start with a fairly good notion of where and what to photograph, and a small series of local guides enables one to make plans and form conclusions. As an instance, we may, having done Charnwood and visited the monastery, approach Leicester by Sanvey Gate, the old *sacra via* used by pilgrims on the way to worship at the shrine of St. Margaret. This church, and at least two others, it would not do to pass by. Then we have a bit of Roman wall and pavement well worth plates. Lutterworth may be mentioned for its connexion with Whitfield the Reformer, and its church can be photographed with only a minute or two’s delay. Between here and Rugby we see English rural scenery at its best. Then Rugby brings up reminiscences of *Tom Brown’s School Days*, and you cannot pass through without a shot at the old school and playing fields, and the church and the doctor’s house, all, with the help of a little imagination, as pictured by the author of that well-known volume; then Warwick, with material for at least six exposures, all on the road, and equally well lighted. Kenilworth will not be far off, but probably we shall push on to Stratford, where, if I have not forgotten, the more interesting features of this painfully clean little town can be successfully got at about midday or early afternoon. But, after all, we may say that these places are within easy reach of home, therefore to be visited at any time; that at present we should get further afield, reserve our energies for the (to us) less accessible places. We can use what time we have to spare better at Gloucester, where, aided by Convention literature, we find ourselves quickly on the track of the best pictures.

At Bristol a ride on the tramway will bring to light several good and characteristic views. Reaching Clifton and along the tortuous Severn we get bits in profusion, but down the Channel we may find it disappointing, for Bristol is not the port many of us imagine it to be; still, weather being propitious, something may fall to our camera—Ilfracombe and Lynmouth, where quaint architecture, lovely coast, and land scenery will charm the camerist. Now, as we get closer to Kingsley’s country, the feverish desire for pictures grows upon one, and, with the mind full of “Westward Ho,” is it any wonder if we become practically hypnotised by the genius of that masterpiece of robust fiction? The fact is, we are on a sort of “Tom Tiddler’s ground,” fairly hemmed in by beautiful form and gorgeous colouring. Well, now, what we felt the want of most is a liberal supply of plates, or, what is better, films. The rule, laid down years ago by the old masters of photography, is one to follow, to duplicate the exposures of the subjects to which we attach the most importance; and here I may give a hint; this is, if using rollable film, do not take these duplicate exposures consecutively—duplicate, but on another sequence of films.

Now, it is clear that, blessed with a reasonable amount of sunshine, we must return with a good bag of results, nor—even though the title of our series be “A Rush through Kingsley’s Country,” or “A Scamper through the Midlands”—need (critics notwithstanding) our pictures display haste and hap-hazard work in their selection and finish, though this is, of course, naturally a matter of temperament and practice. Let six men of average artistic perception perambulate a certain district in search of whatever of the picturesque there may be, and the chances are they will

individually and collectively rapidly find out the finer points. If one can select a better, well and good. It is well to follow one’s own ideas and inclinations sometimes, rather than be bound to the popular conception of such a question as the selection of a picture; above all, do not slavishly follow what I may call the “trade photograph,” nor be over-dismayed if others fail to see the picture which is to yourself clear as daylight.

Now, bearing in mind always that to add to the pleasures of the trip we want to secure the best results possible in the time at our disposal and under the conditions available, we see how desirable it is to have a thorough acquaintance with the capabilities of our apparatus, and to have had, if a magazine camera, plenty of practice with it in the matter of carrying and changing the plates. Another point is to ascertain by previous experiment how far and to what extent we may dispense with a tripod, making use of a time exposure is imperative, a wall, gate, window-sill, and so on. The cycle can be quickly converted into a temporary stand if we provide a light bamboo rod, which may be secured by one end to some part of the steering pillar (and readily held up while riding), one of Lancaster’s or Tylar’s camera clips or carriers being used upon which to place the apparatus during the exposure.

Shutters are still for the most part far from perfect in the range allowed. A pneumatic release for quarter or half-second should be a *sine-quâ-non*. During a recent trip round by Southwell, Newark, and Lincoln, I was able once again to test these requirements, and to prove the adequacy of a one-tenth second exposure for the majority of the plates exposed.

The cycle lamp may add somewhat to the weight to be carried, but is useful if plates are to be changed at night or any other time. It is advisable always to carry a fold of ruby or canary medium as religiously as one should the repair outfit. In the event of a “block” in the internal economy of the magazine camera it is usually possible to have access to a dark room or closet (as distinguished from the photographic dark chamber), and in this, even if daylight be only moderately excluded, a lot can be done with the lamp surrounded by the fold of ruby fabric, the plates can be rearranged or changed without much trouble. It is well to remember also that the cycle *pincho* may be made extremely useful as a rough but ready dark tent. Choose a cape which is large and roomy and fits tightly at the wrists, put it on and fasten it well round the neck, then turn the cape over the head, inside out, that is, and you have all the elements of a dark room (in the old wet days tents were made and used no bigger than this), by the use of which with a little assistance from outside, much valuable time may be saved in the event as aforesaid of a block in the camera from a badly fitting plate or carrier; in the latter case the defect can often be put right by sense of touch only.

J. PIRE.

### PHOTOGRAPHIC DODGING.

FROM time to time photographers are suddenly attracted by some particularly striking photograph which, by reason of the apparent difficulty that must have been experienced in producing it, gives rise to no small amount of curiosity as to how such has been accomplished, and it not infrequently happens that credit is claimed for, and also bestowed upon, a class of work that in point of fact lacks the first element of honesty in manipulation, for such striking effects are not obtained by the means generally stated or implied on the face of such productions.

It is well known that “dodging” is largely practised in photography, and it would be difficult indeed for me to attempt to describe a tithe of the subterfuges to which any one can have recourse to obtain some particular effect or result, and there is little doubt that very much of such dodging is quite within the limits of legitimate photography. There is, however, a class of dodging which goes beyond the line of legitimacy when it is practised with the avowed object of deceiving those to whom such work is displayed as genuine results, and sometimes not only the public, but even Judges at our Exhibitions, are deceived by the artfulness of the modern photographic dodger.

Were such dodging harmless, the practice might be brushed aside as quite beyond being deemed worthy of serious consideration; but, unfortunately, it often leads to much misconception on the part of those who have no knowledge of the possibilities of photography, and not infrequently is found doing an incalculable amount of injury to the professional worker, who is at times requested to produce by honest photography similar results to those which have been obtained by means of trickery, and who, on expostulating and explaining the impossibility of executing such effects, receives the cold douch in the answer, “Oh, Mr. So-and-So, the clever amateur, can do it, and why can’t you?”

This is by no means an uncommon experience with professionals, as many might suppose, and I can well remember a case in point when I was called upon to photograph a horse galloping at the rate of forty miles an hour at close quarters, a feat which even the most experienced animal photographer in Scotland had declared to be an impossibility only a few days previously, but which had been declared to be quite easy of accomplishment by the Mr. So-and-So, so clever with his quarter-plate toy snap-shot camera. I can also call to remembrance other false impressions given to the public from almost exactly similar experiences, among the most recent of which was a striking display of

false golfing and cricket studies, that were so artfully conceived and executed, and for which was claimed the merit of genuineness. Were such results capable of being substantiated as genuine, certainly they would have been trotted out by the manufacturers of apparatus, and would have gone a long way to make the fortune of the party lucky enough to produce the particular shutter that had been used.

I was forcibly struck by a very glaring case of this description quite recently, when I was told by a young lady who did a little snap-shot work that Mr. So-and-So had got a very fine outfit, and was able to photograph a cricket-ball quite sharp when being actually struck by the bat. I don't know in what thousandth part of a second it was claimed that the particular shutter was working, but, of course, you know Mr. So-and-So uses very fast plates. Of course I was sceptical, and expressed a strong desire to see a print from this wonderful negative before expressing any decided opinion upon the marvellous accomplishment. I had not long to wait, however, for soon the young lady brought over the photograph in question. It proved to be an exceedingly well-executed picture.

"How long do you say the exposure was in this case?" I asked.

"Oh! about the thousandth part of a second," was the reply.

"Oh! indeed," I answered. "I should say, with the amount of detail shown in this photograph, as well as the depth of definition rendered, an exposure of about two seconds would be nearer the truth"—a remark which naturally made my fair young friend stare.

The picture in question displayed a gentleman standing at the wickets in a very natural pose, as if blocking a cricket ball that had been bowled in an ordinary manner; behind him was the wicket-keeper, and in the distance could be seen long leg. The ball was almost microscopically sharp upon the surface of the bat—in fact, its very seams could be distinctly seen, and the expression on the faces both of the wicket-keeper and batter was really marvellous, and they must have been thoroughly well in the plot to render such natural expressions. But the paint had been laid on too thick, and the deception was, therefore, only too apparent to any one knowing the actual capabilities of photography. On my openly stating my opinion that the picture was the result of trickery, I was met by the remark, "Oh! Mr. So-and-So is awfully clever, you know, and says that even cannon balls can be photographed in their flight."

Now, in this case I took the pains of investigating into the matter, and found that the ball had been pinned to the bat, and was, just as I had stated, in reality a time exposure, and, fairly judged, was a marvellously good result at that. I have since learned that this picture has been displayed upon the screen, where it also created no small amount of sensation. These things do an incalculable amount of injury when trotted out as examples of instantaneous photography, and which a professional is required to produce so easily.

There is also another phase of this photographic dodging which frequently brings doubt on what, after all, is really genuine work, but which, by reason of the apparent difficulty of execution, is looked upon as trickery. I can well remember a genuine instantaneous picture of a little girl in the act of swinging that was on exhibition, but which gave rise to severe comments for and against its genuineness. In this case, however, the results were derived without any trickery, the whole secret of success lay in making the exposure just at the moment the figure was at its highest poise in the air, and the swing was in the act of turning. Yet there were not wanting those who declared the picture to be obtained by trickery, and a gross injustice was done to the party who so cleverly produced it.

It is also well known that extremely striking results of this kind can be obtained by double printing, such as the introduction of figures leaning over billiard tables, when very long exposures would be required, but no exception can be taken to the cleverness displayed in combination work when it is openly admitted. The evil lies in claiming for pictures that have been produced by means of trickery quite a different method of production, and, as I have said, it very frequently falls heavily upon the honest professional whose reputation does not permit of employing these subterfuges.

A. T. NEWTON.

#### UNITY AND PROFESSIONAL STATUS.

THE Editor, commenting in the June 9th number of THE BRITISH JOURNAL OF PHOTOGRAPHY upon the proposed formation of an association amongst New Zealand photographers, "to encourage unity, and raise the status of the profession," whilst generously wishing it success, is evidently doubtful about the prospects of that success. "The same things," he says in support of his doubt, "have been talked of, written about, and occasionally attempted in England, but absolutely without success." Unity and high professional status are both most desirable things, and well worth fighting for, but they will never, to any appreciably useful purpose, be gained under the present order of things. There are too few photographers, separated too widely in ability and trade standing, in ordinarily sized towns, to get on well enough together to form any local combination that should precede, or at any rate form a natural unit portion of, a wider one. A, in the west end, behind his ample plate glass, catering for richer clients, is not disposed to put him-

self upon equal terms with B in the high town. B, in turn, although holding himself to be quite as capable and good a man as A, if not a better one, thinks himself decidedly superior to C, lower down the town, and out of the main street. By the time we get to about G, with a display of faded prints in a cottage window, and a shed studio in an overlooked small back garden, we are altogether beyond the psychological possibilities of equality. Or one cuts prices, the other is the coupon man, a third is anathema, owing to something else, and so the little comedy of photographic life goes on. The same state of things applies more or less in many other directions, amongst chemists, doctors, dentists, and lawyers, who rarely strain themselves in saying anything good of each other. There is, however, one material difference in the case of these latter, in that each has passed the same stiff qualifying examination as his fellow, a leveling factor in their intercourse that in turn tends to bind them together. It would be too much probably, carrying the inference logically out, to demand a compulsory qualifying examination for photographers. In the cases referred to the examinations are primarily, it must be admitted, for the protection of the public more than the gain of those who go in for them, although the latter object is at the same time incidentally served. This necessity does not obtain in the case of the photographer, who, in the event of mistaken treatment of a client, does not, as in the case of the doctor or chemist, say, lay himself open to the possibility of having to square the coroner. It must also be further admitted that the main object aimed at, hard-and-fast money gain, is, granted fair technical ability, more dependent upon a pleasing personality and a knowledge of human nature than high place in an examination list. Still the fact remains that the much be-damned examination is the only recognised practical means of giving a status. Now, as a matter of fact, has the photographer, taking him "by and large," a professional status at all? No; although it is readily admitted that, in many cases, knowledge and skill rise so high that their possessors may in all fairness claim rank as high as that of the members of any profession—medical, legal, or what-not—but, in the main, the term professional, beyond distinguishing between the man who gains a living by the practice of photography and the one who doesn't, is a misnomer. Trade skill, and that of no particularly high order, would be a more correct term. It takes very little to make the ordinary photographer, and the general cheapening down of work, and all the complaining thereat, is directly due to this fact. The entrance gates are hung too easy, and the way through has too much of the easy breadth of the Scriptural one leading to much the same place that the trade is going to, according to those engaged in it. Photographic work, to those not professionally engaged in it, is seen clearly enough to form no exception to the general rule that work always fetches exactly what it is worth. The art is not old enough yet to have lost sight of the high first prices, and comparisons of present ones with them are misleading. It took far more to turn out work then than now; there were fewer engaged in it, and it had, further, the adventitious aid given by the dark-room air of mystery surrounding it in the popular imagination. The comparison should be made, instead, between the prices of to-day, and the time and trouble it has taken the worker to gain sufficient skill and knowledge to do his work. According to this standard photography is paid even a trifle higher for than its value. The introduction of the personal element in the buyer affects him. A man in the case of his own photograph, or that of his wife, child, or sweetheart, is not so keen about gauging its market value as he is of what he buys from his grocer or draper. It is unconsciously held to be not quite the thing to inquire too closely into prices, more than into his whisky and cigar bill, or what he spent altogether upon his holiday, always provided, of course, that they were good and enjoyable. Not that it is thought for a moment inadvisable to try and lift prices; the best effort should be made to do so, but by lifting the quality of the work. This, in isolated instances, can be, and has been, done by the individual; and many classical photographic names will readily suggest themselves as linked with classical prices. But generally, to benefit the many, it can only be done by a systematic effort to confer upon photographers something in the way of the professional status that they as a body lack. Reducing numbers arbitrarily is, of course, out of the question, as trenching upon the far more important, almost sacred, question of personal liberty; reducing numbers by the natural, slower, evolutionary process of weeding out the less fit there can be no objection to. The public will do the weeding, as it has already done in many other directions, and is more insistent upon doing daily in fresh ones. Examination, and the training it presupposes, are the best practicable means for the gaining of that true vigorous growth in the photographic field that will mean a fair chance in the weeding process. It is not a thing that can be introduced suddenly, more than compulsorily, but, like all natural ones that come to stay, must be done gently and gradually. Photographers in business would not entertain for a moment going in for an examination without a distinct, palpable, and immediate gain in view. But few reasonable men would refuse to give weight to a certificate presented by an assistant applying for a place, showing that he had passed an examination in practical work before a recognised board. The assistants of to-day will soon be the masters, and in turn still more likely to look for a higher standard in their assistants. As it is, what test has the master of the capacity of an applicant for a place? A few samples of work done, and these, naturally enough,

the selected—often accidental—best, instead of the desired normal. He is given a trial, fails to work regularly up to his samples, has to leave, and fills up his spare time before he can get another place by grumbling privately and publicly at the woes of assistants and the sine of masters. But is it likely that a photographic master, more than any other, would lightly part with a good man? Hardly. The assistant must not be pressed upon too heavily either. It is not altogether his own fault. He hasn't a standard to work up to and measure himself by. If he had, he would respond, at least the best would, and they are the ones it is desired to catch. Give him the chance in an examination. The rather chaotic character of photography and its processes have hitherto been a great bar to the idea perhaps, but it is rapidly emerging from this state, and there is quite enough of the definite on hand now to form a good solid foundation for an examination. An examining body, selected by an acknowledged authority, which would examine candidates in the necessary theoretical principles of optics and chemistry, and practically in the leading photographic processes, is practicable enough; and a fee of a couple of guineas would cover expenses.

This for a start; what it might lead to is another question, certainly to a desirable broadening all round. Authoritative lectures on art as applied to photography possibly, that might lead photographers with a text-book smattering of art to be more patient laterers than they are, when painters and artists who have made an absorbing life study of it are talking, and, as patient listeners and interested learners, to mutual gain warmer friends. A very valuable point gained when one thinks of the wasted time and misdirected effort now spent in trying to make an out-of-focus photograph look like an artist's work, and smudges impressionist pictures.

Lectures on pose and background, again, would mean fewer crimes in show-cases and windows, and a realisation of the fact that one need not necessarily look unlike himself in a photograph. There is, in short, no end to the advantages that a systematic diffusion of the knowledge now possessed by the few would result in. Finally, and to the essential material end, the public would not be slow in noting the improvement, or unready in paying a better price for the better article. J. REES.

### THE THEORY AND PRACTICE OF EXPOSURE.

THE articles on exposure meters and the speed of plates that have recently appeared in our pages may be supplemented by the following notes of a lecture by Mr. G. F. Wynne on the theory and practice of exposure which that gentleman recently delivered before the Manchester Amateur Photographic Society. We are indebted for the extract to the *Photographic Record*, the Society's well-conducted quarterly organ.

The lecturer said that in his boyish days he was a worker with the old collodion process, and still preserved a few of the negatives taken by himself about the year 1867. He took up the photographic theory again about 1885 on a visit to Norway, where, owing to errors in exposure, through inexperience, the very great majority of the negatives he took were failures.

Afterwards he derived some aid from exposure tables, but could never be certain that the correct exposure was being given, especially under any exceptional circumstances.

About the year 1890 he experimented with a very simple actinometer, made out of a Beecham's pill-box, and found, as a result of experiments, that there was a certain sized stop through which every plate received the correct exposure in the same time that the actinometer paper took to darken to the standard tint. The slower the plate the larger the diaphragm required, and the quicker the plate the smaller the diaphragm required.

These experiments gave him the idea to formulate a list of plate speeds, in which, instead of expressing the sensitiveness of the plate by an arbitrary number, it should be expressed by the size of diaphragm through which the plate would require the actinometer time for its correct exposure under normal conditions.

From this resulted the exposure meter which bore his name, and of which he felt truly proud from its almost universal recognition by the great body of amateurs.

The lecturer said that to a professional photographer, working in his own studio upon the same kind of subject, the same plate, and generally with the same diaphragm, and having a large practical experience, an exposure meter was not a necessity to ensure uniformly good results.

With an amateur, however, the case was entirely different. He went in for work of the most varied description, from the taking of a breaking wave in the one-thousandth part of a second, to photographing a dark church interior in perhaps three or four hours, the latter subject requiring an exposure about 12,000,000 times more than the former.

Dealing with the question, "What is correct exposure?" the lecturer explained that according to his idea of the matter, correct exposure is the exposure given to any negative which, when it was developed with a normal developer, would give in the resulting print the most correct reproduction of the contrasts of light and shade present in the original subject when photographed. If a negative be under-exposed, these contrasts are unduly accentuated with an absence of detail in the

shadows, and, if over-exposed, the contrasts are diminished, the negative being full of detail but flat.

If the contrasts in the subject to be taken are very great, such as in an interior brilliantly lighted with sunlight, and yet having portions in deep shade, or to take another subject, say, of sea and sky with a heavy foreground of trees or houses, the scale of those contrasts cannot possibly be correctly represented by the light and shade scale of the print, the utmost range of which is from white paper to black pigment. In such a subject, and in many others, the exposure must be a compromise, a longer or shorter exposure being given, according to whether the extreme shade is the most important to be correctly represented. Indeed, it is in the question of the variation of exposure due to subject, and the variation necessary to produce the particular effect required, that the amateur is able to exercise his judgment and his powers of reasoning.

The exposure meter, however, for all normal subjects, will give the correct exposure without any calculation whatever, and any variation from this required by the particular subject or the object in view, may be made by the exercise of the amateur's judgment.

The lecturer, dealing separately with the four factors of exposure, viz., light, stop, character of subject, and sensitiveness of plate used, amplified the instructions given in the book with the exposure meter, and by means of the large model worked out several exposures from various assumed values of the factors of exposure.

In regard to the matter of the testing of plate speeds, the lecturer explained that the latitude possessed by nearly all the good brands of plates was so great that only an approximate idea of the speed could be formed by taking an actual photograph.

He had therefore specially designed a simple instrument for testing the speeds of plates, which he exhibited and explained to the members. It consisted essentially of a piece of wood about three inches thick and the size of a half-plate, perforated with a number of holes about three-quarter of an inch diameter. At the top of this perforated block was fitted a sheet of black celluloid in which were a number of graduated perforations, one perforation being over the centre of each of the before-mentioned holes in the block.

The areas of these perforations were graduated in exactly the same geometrical ratio as the scale of diaphragms in the meter, viz., in the progression 1, 2, 3, 4, 6, 8, 12, 16, &c. Over the bottom of the holes in the block was fixed a piece of tracing cloth, or other translucent material, carrying the figures of the scale of diaphragms.

Firstly, having found by experiment that negatives on, say, a Paget Phoenix Plate, were correctly exposed on a normal subject through stop *f*-45, in the actinometer time, and, secondly, that the same plate exposed in the speed-testing instrument to the light of a standard candle, at a distance of two feet for forty seconds, when developed, just showed the number *f*-45, and no higher. The testing of any other plate was a matter of the greatest simplicity, as, if a number of plates were exposed in the instrument exactly in the same way, the highest figure which on development could just be read would indicate the actual and comparative speed of the plate itself.

Mr. Wynne stated that he had personally tested within the last few days every negative plate of English manufacture, and he exhibited a large number of these, the speeds of which varied from *f*-14 to *f*-111, the latter plate being sixty-four times as quick as the former.

Referring to the claims made by the compounders of certain special developers that by their use the speed of a plate was doubled, all his experiments went to disprove this assertion, as he had personally never found that any of them which he had tested would bring up or render visible a higher number on the plate when tested with his sensitometer than was the case with the developer he always used, viz., pyro ammonia with metabisulphite of potash.

### HUNTING FOR PLATINUM ON THE BEACHES OF CALIFORNIA AND OREGON.

[Paper read before the Photographic Society of Philadelphia.]

I HAVE recently made a business trip in the Far West—California, Oregon, Washington, British Columbia, and the North-west Territories—in search of platinum, and your Lantern Committee has been good enough to think that some of the snap-shots that I have made to show the occurrence of platinum in the auriferous sands of the river beaches and the Pacific coast may be of interest. Some of them have no merit whatever, other than that they fairly represent the peculiarities of placer mining; some were made from the car window, some were made in the rain, some were made in the very early morning, or about sunset, and others when I had all the time I wanted and everything was favourable.

Platinum was first found, I believe, in the alluvial deposits of the River Pinto, near its mouth. The River Pinto is in the United States of Columbia, and empties into the Pacific Ocean at Choco Bay. At the present time the supply of platinum is mainly drawn from Russia. The total output of the Russian mines for the year 1897, the last for which there is a public record, was about 174,000 ounces, troy, while the platinum mined in the United States and Canada for the same period of time would be, I presume, about 500 ounces. Platinum is found in

nature in the form of scales, and sometimes in the form of lumps or nuggets. It is reported that a nugget of platinum weighing twenty-six pounds was found in the Ural Mountains. There is also a report of the finding of a platinum nugget in South America weighing about eight pounds. The largest nugget I have found on this trip weighs about one half ounce. Platinum has a specific gravity a little higher than gold. It is ordinarily non-magnetic, ductile, and is soluble only in heated aqua regia.

... I began my hunt for platinum in the north-western part of California. With an ordinary shovel a small quantity of black sand is removed from the bed of the stream in which it is supposed that platinum may be found. This is put into a miner's pan, which is made of heavy sheet iron, about the size and shape of an ordinary milk pan used by farmers. The pan is afterwards filled partly with water, and the contents agitated, so that the heavy particles of earth and sand will settle to the bottom, and the lighter particles rise to the top and be floated off with the water. Small pebbles, &c., large enough to be taken out with the hand, are removed in that way, and the operation is continued until the heavy material is settled in the bottom. This heavy material will consist of iron, gold, platinum, &c., the presence of which can be determined without trouble with the naked eye. By careful use of a magnet most of the magnetic iron can be removed. Great care is necessary, however, as, while pure platinum is non-magnetic, yet, as the grains are small, it may be mixed with the iron mechanically and lost. The gold is separated by the use of quicksilver. It is not necessary, in performing the mechanical operation termed panning, that a pan should be used. This operation is very frequently done with an ordinary shovel, and miners become very expert in the use of the shovel or the pan in separating the above-mentioned materials. Mining in a large way is done with water under pressure, and is termed hydraulic mining. . . . The water for this particular mine is brought about thirty miles, siphoned across a valley something over 200 feet in depth, and is delivered at the nozzle at a pressure of 175 pounds to the inch. . . . The nozzle is seven and a half inches in diameter. By a suitable arrangement the direction of the stream from the nozzle can be changed as directed, and the earthy bank is washed down to bed rock. . . . The large boulders are removed at proper periods, and the finer particles are carried with the waste water through a sluice or flume. The bottom of this sluice is usually paved with wood, after the ordinary method of paving streets. The interstices between the blocks of wood, however, are much greater than if the blocks were laid for street paving. In the sluice, towards the lower end, a suitable quantity of quicksilver is placed, and, by the action of the water, is reasonably well distributed in these interstices between the blocks, the gold that is carried down the sluice amalgamates with the quicksilver, and at intervals is removed, the quicksilver and gold being then separated in the ordinary way. At the lower end of the flume the bottom of the sluice is covered with copper plates, silvered, and any gold that may have passed the sluice without being amalgamated is retained by the copper plate. If the platinum is to be saved, the sluice beyond the part covered by copper plates is covered with a blanket, and the platinum, which is ordinarily in the form of flat scales, is retained by the nap of the blanket. The iron, garnets, monozite, and other heavy material, which is usually round in form, is carried by the force of the water over the nap and into the dump heap below. The blanket used is made so that it can be taken out at any time, and the platinum beaten or shaken off on to a sheet. This is the ordinary method of saving platinum, rather crude and very wasteful. There are several devices for doing the work in a much more scientific and economical way. Platinum is ordinarily found in the beds of streams or ancient river beds, in the vicinity of serpentine or chromite rock. . . . In hydraulic mining there is very considerable difficulty in getting rid of the earth, sand, and gravel, and a few years ago there was an active and bitter fight between the farming and mining industries in California, the principal question of politics hinging on the "Debris Law." On the east side of the Cascade Mountains no hydraulic mine is permitted without complying with the law regarding the overflowing of agricultural lands, but on the west side there are practically no farming lands, and not much attention is paid to the law. The present surface of the bed of a branch of the Trinity River is thirty-seven feet above the original level when mining operations were started. Wherever there was a ranch, the mining company has purchased the land from the proprietor to prevent litigation. In some mining operations, owing to the formation of the ground, it is quite difficult to get down to bed rock and have room to make the proper sluices. In some large mines extensive blasting operations have to be gone through with.

COLONEL W. E. BARROWS.

#### HETT'S DAYLIGHT CHANGING SYSTEM.

MR. CHARLES LOUIS HETT, the well-known mechanical engineer, is the author of this device, which he thus describes:—

"Each sensitive plate is placed in a separate light-tight bag of leatherette, or other suitable material. These bags are about double the length of the plate, and are closed by a double crease in opposite directions. The film side of the plate is distinguished by a mark on the outside of the bag.

"As a further protection from light, the bags, when loaded, may be stored in outer bags or boxes, the latter being generally the more convenient plan.

"For placing the plate in the camera or dark back I employ a special transfer chamber about the length of the plate employed, or rather more.

"The section of this chamber is a flat oval, with suitable grooves to receive the plates. The upper end is open, and the lower end is closed by a sliding or revolving valve. The form of this valve, and the connexion between the transfer chamber and the camera or dark back may be varied; but I prefer the arrangement shown on the drawing.

"In the accompanying drawing my invention is shown as applied to a camera. In the case of a dark back, but little modification is required beyond the introduction of the ordinary sliding shutter.

"Fig. 1 is a back view of the camera with the transfer chamber in position for inserting a plate. Half is in elevation, and half in section. Fig. 2 is a longitudinal section. Fig. 3 is a plan, half in section, and

half with the transfer chamber removed. Fig. 4 is a plan of an automatic arrangement for pressing the plate against the front of the frame, and thus bringing the film into register.

"A is the plate when in the bag, B, which is placed on the transfer chamber, C, and secured thereto by means of an indiarubber ring, D.

"This ring is circular in section, so that it may readily be rolled from the lower part of the transfer chamber on to the mouth of the bag, or in the reverse direction. A' represents the plate when in position in the camera or dark back; E, E, are hooks on the transfer chamber, which, when the latter is in position, engage with the lugs, F, F, and hold the transfer chamber securely to the camera or dark back; G is a valve which closes the lower end of the transfer chamber, when removed from the camera or dark back; I is a valve which closes the opening in the camera at the same time; H and K are small springs which keep these valves from shaking open; L is the frame containing the plate when in the camera or dark back.

"The mode of operation is as follows:—

"When it is desired to place a plate in the camera or dark back, the outer crease of one of the bags containing a plate is straightened out, and the open end of the transfer chamber inserted into its mouth, taking care that the mark on the bag, indicating the film side of the plate, corresponds with a similar mark on the transfer chamber.

"The indiarubber band, D, which has previously been placed on the transfer chamber, is rolled over the mouth of the bag, holding it tightly, and effectually excluding the light. The transfer chamber is now

attached to the camera, or dark back, by applying it thereto and sliding it in the direction of the lens.

"As the transfer chamber moves it carries with it the valve, *i*, and thus opens the aperture in the camera, or dark back. While the transfer chamber moves the valve, *g*, remains stationary, and thus the lower end of the transfer chamber is opened. The bag, *b*, is now turned vertically upwards. This opens the remaining crease, and the plate drops into the camera, or dark back. The film is brought into register by a light-tight screw through the back, by any suitable arrangement now used for a similar purpose, or by the arrangement shown on the drawing which I now describe. *m* is a set screw tapped into and, therefore, moving with the valve, *i*. *n* is a yoke jointed at each end to levers, *o*, *o*. There is a stop on each end of the yoke, *n*, which bears against the levers, *o*, *o*, and the yoke is thus prevented from falling too low. *p*, *p*, are two springs bearing on the levers, *o*, *o*, and pressing them towards the plate, *a*<sup>1</sup>. *r* is a centre pin, carrying the two levers, *o*, *o*. *s* is a stay, a duplicate of which, not shown on the drawing, is on the other side. These stays support the frame carrying the plate, and also form packings between the cover plates, *t*, *t*, and the frame. *u* is a packing for the like purpose. The effect of *s* and *u* is to separate the cover plates, *t*, *t*, from the frame, and to leave room for the working of the levers, *o*, *o*.

The transfer chamber is shown in position, and the pin, *m*, acting through the yoke, *n*, holds the lower ends of the levers, *o*, *o*, clear of the plate, *a*<sup>1</sup>.

The transfer chamber is removed by sliding it backwards away from the lens, until the hooks, *e*, *e*, clear the lugs, *f*, *f*. This action closes the valves, *g* and *i*. The valve, *i*, in closing, leaves the yoke, *n*, free to move away from the lens, and consequently allows the springs, *p*, *p*, to press the lower ends of the levers, *o*, *o*, on to the back of the plate, *a*<sup>1</sup>, thus bringing the film into register.

The removal of the plate is effected by replacing the transfer chamber and reversing the above operations.

### THE PHOTOGRAPHY OF ANIMALS IN MOTION.

A NEW edition of Mr. Muybridge's book on animals in motion has just been issued by Messrs. Chapman & Hall. The work of this eminent photographer was at one time very imperfectly appreciated and understood; but modern critics appear more disposed to rate it at its just value. One of them remarks that the book contains "a series of photographs taken at rapid intervals, and, arranged in line consecutively, display the different movements of walk, trot, gallop, and so forth, in a number of different animals." We have illustrated here in oblong-shaped plates the ponderous gait of the elephant, the furtive stalk of the tiger, and even the suspended sloth. The human species is represented by "an athlete;" flying and walking birds show their paces, and a kicking mule completes the list of the principal diversities of animal locomotion and motion. The facts gathered by Mr. Muybridge enable him to criticise many statues and pictures, both ancient and modern. It is pleasing to find that many of the great artists and sculptors come unscathed out of the ordeal. The real artist, who can and does observe, sees the varied movements as they really are; the inferior craftsman is apt to put the conventional notion instead of the real appearance.

It has been held, apparently, by some that the horse cannot only walk, amble, trot, canter, and gallop, but that there is a faster pace still, to which the name "running" has been given. Careful photographs and a comparison of the succession of the feet in movement shows that no such "pace" exists. The gallop itself has been singularly misinterpreted by the moderns—by many of them at least. The author is compelled to use harsh terms, and to say with some truth that such illustrations "exhibit an entire absence of careful observation, unprejudiced impression, or serious reasoning." The type to which he refers is well exhibited by the leaden horses in a game once prevalent, that called the Race Game, where jockeys mounted on horses progress slowly over a marked cardboard racecourse; the horses here are elongated, the heads stretched out, the fore feet well to the fore; the hind feet equally extended behind. Such an attitude never occurs in the galloping horse. On the other hand, a frequent representation of this pace is seen in statues where the animal has the hind limbs planted on the ground and the fore limbs elevated as if to jump; this, rather curiously, is an accurate picture of one of the phases of the gallop.

### PATENTS IN 1898.

THE report of the Comptroller-General of Patents for the year 1898 has just been issued. For the first time since the Act of 1884 came into force, points out the *Journal of the Society of Arts*, there has been a distinct falling off in the number of applications for patents, the applications in 1898 numbering 27,659 as against 30,952 in 1897, a decrease of 3293, or 10·7 per cent. In the year 1895 there was a falling off as compared with the previous year, but the difference at that time was a little more than 300. The Comptroller considers the rapid growth in the number of applications which took place in 1896 and 1897 was to be attributed to the

activity of the cycle industry, and that there is little doubt that the decline in that industry has caused the present decline of numbers.

As the 1884 Act has now been in operation for fourteen years, the earliest patents granted under it have run out their full time. It appears that 5·5 per cent. of the 1885 patents have been maintained for the full fourteen-year period; the proportion of the previous year, 1884, was 4·5 per cent. The average percentage of patents granted under the 1882 Act which ran for their full term was 6 per cent., so that the conclusion may fairly be drawn that the reduction of initial fees in 1884 has only slightly diminished the average value of the patents sealed, while it has added considerably to their number.

Of the total number of applications, 17,389 come from England and Wales, 1395 from Scotland, and 502 from Ireland. There are only three foreign countries from which large numbers of applications come—2629 from the United States, 2599 from Germany, and 1133 from France. There are only eight other countries from which as many as 100 applications come.

An elaborate table, printed as an appendix to the report, shows the different classes under which inventions may be arranged for the period of 1884–97. Later figures cannot be given, on account of the time which may elapse before the acceptance of a complete specification following on an application. There has been a great increase under certain of the chemical classes, attributed to the development of the acetylene industry, which is also responsible for a large increase under lamps. In the following classes the number of patents is said to be practically stationary: Agriculture, guns and ammunition, sanitation, ships, and textiles. There has been a decrease as regards iron and steel, cutlery, and steam engines, and a considerable increase in advertising, electric lamps, and photography. Since 1884 the inventions relating to the cycling industry have increased sixfold, but the advance in 1898 was barely maintained in 1897. The numbers for 1898 are not yet fully available, but it is believed that the extraordinary inventive activity in this industry has reached a climax, and now gives signs of abatement. As might be expected, an unusually large number of valueless inventions appear to be included in this increase. Of 6000 applications made in 1897 in connexion with cycles, only 2300 were completed—much less than the average. An increase in air and gas engines is attributed to the number of inventions for oil engines intended for motor cars. Here, however, there is a decline in 1897, which appears to be continued in 1898. Among minor industries, hatmaking and tobacco show substantial increases, and sugar and watchmaking substantial decreases. Since the passing of the Workmen's Compensation Act the number of applications relating to guards for preventing accidents with machinery has very largely increased. Immediately after the railway accident at Wellingborough Station, caused by a luggage truck falling on to the line in front of an express train, there was a great increase in inventions for railway platform luggage trucks. As showing the relation between passing events and the course of invention, it is mentioned that the publication in a London morning paper of a letter relating to the waste of horse feed in London was followed within five weeks by thirty-four applications for patents for nosebags for horses, the average number per annum being about twelve.

## Our Editorial Table.

### TASCHENBUCH DER PRACTISCHEN PHOTOGRAPHIE.

Gustav Schmidt, Berlin.

THIS handy little volume has entered upon its fifth edition, and, as the first made its appearance in 1891, Dr. E. Vogel may regard this fact as substantial proof of the usefulness of his work. The directions and formulae are clear and concise, and Dr. Vogel has freely illustrated the book, to give the reader a clear insight into the subject. In each branch the work has been brought well up to date.

### JAHRBUCH FÜR PHOTOGRAPHIE UND REPRODUKTIONSTECHNIK, 1899.

Wilhelm Knapp, Halle a/S.

THE thirteenth volume of this valuable record of photographic work has reached us, and subscribers will not fail to appreciate the large addition Dr. Eder has been enabled to make to its pages. The original articles touch upon many important subjects which have excited the attention of photographers during the past year. As might be expected, the latest innovations in photo-mechanical work form an important feature of the volume, and in this respect the illustrations at the end add largely to the value of the book. Amongst the contributors we notice the names of Dr. G. Aarland, Ph. Ritter von Schoeller, Dr. J. Husnik, Raimund Rapp, Aug. Albert, Dr. Andresen, A. von Hübb, Professor Valenta, Dr. Mieths, J. Gaedicke, and many other leading Continental workers. The record of the year's progress is arranged according to subject, and is very thorough and complete.

## News and Notes.

THE South London Photographic Society's eight days' tour in Ireland (Royal Meath and County Wicklow), including sixty miles of driving, takes place July 21 to July 30.

THE Bootle Photographic Society's Sixth Annual Exhibition of photographic work will be held in the Masonic Hall, Merton-road, Bootle, Thursday, Friday, and Saturday, October 26, 27, and 28. All entries and other communications to be addressed to the Hon. Secretary, Mr. Thomas A. Dodd, 188, Strand-road, Bootle, Liverpool.

MESSRS. TAYLOR, TAYLOR, & HOBSON, of Leicester, write: "Our business having outgrown the capacity of Slate-street Works, we have erected new factory and office buildings, to be known as Stoughton-street Works, Leicester. These buildings, equipped with every modern convenience, will, we trust, enable us to improve our products and to execute orders with greater despatch."

PHOTOGRAPHIC CLUB.—Anderson's Hotel, Fleet-street, E.C., Wednesday evening, July 19, at eight o'clock. Discussion, "The New Photographic Printing Papers." Visitors are admitted to the meetings of the Club on the personal introduction of a member, or by invitation cards, which the Hon. Secretary (Mr. W. R. Stretton, 4, Queen-street-place, E.C.) will be pleased to forward on application.

THE very latest X-ray story runs as follows:—Mr. John Foster, a Cleveland millionaire, was suffering from a serious abdominal ailment, and the doctor made him swallow an indiarubber bulb, covered with a photographic film, which was inflated until it completely filled the stomach. An X-ray exposure was then made, the film withdrawn, and an excellent photograph of the interior of the stomach, revealing the presence of a large tumour, secured.

SELECTION COMMITTEE FOR THE AMERICAN INSTITUTE SALON.—The following photographers and artists have consented to act on the Selection Committee for the Salon of the American Institute: Pirie Macdonald, Albany, N.Y.; Rudolf Eickemeyer, Yonkers, N.Y.; E. Lee Ferguson, Washington, D.C.; Hinsdale Smith, Springfield, Mass.; Francis C. Jones, N.A., New York City; Alexander Black, Brooklyn, N.Y.; E. Wood Perry, N.A., New York City; W. Granville, Smith, New York City. It will be noted that two of these are artists of high standing, but both of them are photographers as well as painters.

LORD SALISBURY AS CHEMIST.—Lord Salisbury, whose intense interest in chemical research knows no lull, has, declares the *Medical Press and Circular*, discovered and completed an important chemical process in his private laboratory at Hatfield. The results, according to this journal, will be made known to the world on his behalf at a forthcoming meeting of one of the learned societies. The scientific world has for long known that it had in the English Premier a devoted student to chemical science. Despite the arduous duties attached to his official post, he, nevertheless, snatches every available opportunity of prosecuting his favourite study.

THE South London Photographic Society's Third Continental Excursion to Belgium takes place from August 19-27. The leaders are Messrs. William F. Slater, F.R.P.S., and Walter D. Welford, F.R.P.S. The estimated total cost is 3*l.* 16*s.* (including saloon on boat). An attractive programme has been prepared. The leaders have been able to obtain considerable reductions both in hotel charges and railway fares. It is expected that a meeting will be arranged with the Brussels section of the Belgian Photographic Association, on one of the evenings, which will be entirely of a social nature. All members of other societies are invited to the excursion. Any further particulars may be obtained from Mr. William F. Slater, 5, First-parade, High-road, Lee, London, S.E., or Mr. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.

SUNDAY TRADING.—John Hawkey, photographer, of Humber-street, Cleethorpes, pleaded guilty, at the Grimsby Police Court, to having traded on a Sunday. Defendant admitted that he was open. He had been used to open on a Sunday, and, as a matter of fact, Sunday was the best day for photographers. People could get a bath, refreshments, cigars, or have a ride on Sunday at Cleethorpes, he thought they ought to be able to get their photographs taken. Fines 1*s.* and 5*s.* 6*d.* costs. Defendant said he would pay 5*l.* for a special licence to open on Sunday. There was a similar charge against R. Gildershaw, of 61, Queen-street, Cleethorpes, who keeps some sort of a menagerie. Superintendent Stennett said that he found defendant was not able under the Act under which he had been proceeded against, although he might be liable under another Act. The charge would be withdrawn.

THE BICHROMATE TRADE.—With regard to the making of bichromate of potash, which is widely used in dyeing and in other manufactures, there is no doubt, points out Dr. Andrew Wilson in *The Weekly Scotsman*, the trade is an unhealthy one. The particles of dust arising from the powdering and firing of chromic ironstone act on the lining membrane of the nose, and occasion with destruction of the partition (or septum) between the nostrils apt to occur. But Dr. Arlidge tells us, in his *Diseases of Occupation*, that precisely the same result occurs in cement-workers, so that some doubt may be entertained that chrome dust is a special agent in producing the disease in question. Then, it is true that on abraded portions of skin ulcers form, owing to the irritation set up by the emanation from the bichromate, and after these have healed "indelible scars remain." Dr. Arlidge adds that "men who handle the stuff best escape the ills of the trade," while subacetate of lead in solution is used as an outward application for the skin eruptions. Undoubtedly chromate works represent places where there is danger to the workers involved in their labours, just as needle-grinding and white-lead working are also accounted very unhealthy trades. It remains for science, the wiser, and, above all, for the common philanthropy of employers, to abate the ills complained of. That they will abolish them utterly is a hope not to be entertained this side of the millennium.

INCANDESCENT GAS MANTLES.—The commercial incandescent mantles of to-day are composed almost entirely of oxide of thorium,  $\text{ThO}_2$ , to which has been added a small quantity of oxide of cerium,  $\text{CeO}_2$ , varying from 0.5 to 2.0 per cent. With the exception of a small quantity of lime they only contain traces of impurities, such as nitrate of thorium, and oxides of zirconium, neodymium, lanthanum, and yttrium. To satisfy himself that these impurities have no appreciable influence on the luminous power of the mantle, the author has undertaken a series of photometric measurements, from which he has been able to establish the following conclusions: The oxides of zirconium, lanthanum, and yttrium do not increase the illuminating power of the mantles. Oxide of neodymium increases it to a slight extent. The admixture of 1 per cent. of the oxides of zirconium, neodymium, lanthanum, or yttrium, has no influence on mantles containing 0.5 per cent. of lime. The lime contained in the mantles, doubtless, comes from the ash of the tissue used in their manufacture. As this substance increases the fragility of the mantles, it should be eliminated as far as possible.

BOTH the chemists and photographers of the Rochdale district have heard with very great regret the news of the death of Mr. Hermann Bamford, the well-known chemist and druggist and Secretary of the local Photographic Society. Mr. Bamford had a very short illness. He caught a chill, and on Sunday of last week pneumonia set in. He gradually grew worse, and died on Tuesday evening of last week. Mr. Bamford's death, at the early age of thirty-one years, has come as a sad shock to his many friends. He leaves a widow and one child. Dr. Hodgson was deceased's medical attendant. Mr. Bamford was the youngest son of the late Councillor Bamford, and was associated with his brother, Mr. William Bamford, in the chemist's business which they carried on in Yorkshire-street under the title of "The Executors of the late J. W. Bamford." Deceased took great interest in photography, and was well known in the town and district as a magic-lanternist. He had been actively identified with the Rochdale and District Photographic Society from its inception, and for several years prior to his death he acted as Secretary of the Society. He had been connected with the Providence Congregational School from his childhood. Mr. Bamford was a man of quiet, unostentatious demeanour, and was warmly esteemed by a large circle of friends. The funeral took place on Friday afternoon last at Heywood Cemetery. It was an unostentatious ceremony, only the nearest relatives and friends being present. The Rev. B. W. Jackson, of Providence Chapel, conducted the funeral services both at the house and at the cemetery. The coffin was covered with wreaths. Messrs. Barton & Son had charge of the funeral arrangements.

SOME OLD PRINTING PROCESSES WORTH TRYING.—"By way of experiment, or perhaps amusement, or maybe, after all, with the hope of modifying some of the old printing processes, so as to make them available by the light which the new photography may shed upon them, I have been ransacking the old books for forgotten formulæ, and have had some very good results, which some of your readers may like to try," writes Mr. Hahn in the *American Journal of Photography*. "Here is one worth trying, which furnishes quick-printing paper: Float the paper for five minutes on a solution of bichloride of mercury; saturated solution of bichloride of mercury, 6 drachms; water, 1 pint. When dry, float in a darkened room in a silver solution, 40 grains to ounce. The exposure required is about five seconds in sunlight, or a minute in dull weather, until a faint image is produced, then develop with: Sulphate of iron,  $\frac{1}{2}$  ounce; water, 1 pint; glacial acetic acid, 1 drachm. Wash and fix with hypo. In place of the iron developer very dilute metol, or para-amidophenol, may be used with good effect. These prints need no toning and are quite pleasing in colour. Another process, long forgotten, gives most beautiful results: Take syrup of iodide of iron (which may be had at the apothecary's), distilled water, each 2 drachms; tincture of iodine, 10 drops, and mix. Brush over one side of well-glazed paper, and, after a few minutes, dry with blotting-pad and then wash with nitrate of silver, 1 drachm; distilled water, 1 ounce; and dry in dark. Expose in a printing frame, when a latent image is formed, which all that is required to develop is a wash in pure water and preservation for a short time in the dark, varying with the degree of exposure. The exposure induces an action which is carried on in the dark. After the image is completely evolved, the free silver is eliminated by fixing in hypo."

THE PROPER READING DISTANCE.—"At a distance of several metres or yards," says Dr. Norburne B. Jenkins in the *Medical Record*, "little or no muscular effort is required for the normal eye to see objects distinctly; but an extreme exertion of the ciliary muscle, which controls the crystalline lens, is necessary if the vision be directed to an object a few centimetres or half-inches distant from the eye. The following may illustrate the work of the muscles of the eye in reading at several distances: A sheet of paper about twenty centimetres (eight inches) square, printed with type sufficiently large to be easily read at five or six metres or yards, is placed at this distance from a person with normal or emmetropic eyes. Practically no contraction of the muscles of convergence or of the ciliary muscles is necessary in order to read the type. Should the paper be placed a metre or yard from the eyes, the ciliary muscles and the muscles controlling the motions of the eyeballs are called upon for additional work, but no inconvenience is occasioned to emmetropic eyes by prolonged vision at this distance. If the paper now be placed within a few centimetres or half-inches of the eyes, the ciliary muscles contract to their utmost. The internal recti likewise are in a state of extreme exertion in accomplishing the convergence necessary in order that both eyes may see the same type at the same instant. The muscles are no longer adequate to the increased tension. They become exhausted and vision is embarrassed. The type is alternately blurred and distinct, in consequence of the alternate failure and recovery of the muscles. Should this process continue for many minutes, pain and vertigo come on, and the sufferer is forced to direct his vision from the paper. The nearer objects approach the eyes, the greater will be the necessary muscular effort and the sooner will the muscles refuse to perform their functions; the farther the type is held from the eyes, the less is the requisite muscular effort; hence it is probable that the farthest point at which distinct reading vision is possible is the proper distance for continuous read-

ing. Probably this point is more than thirty-five centimetres (fourteen inches) distant from the eyes, and is dependent upon the strength of the muscles, habit, and the visual acuity."

## Patent News.

The following applications for Patents were made between June 26 and July 1, 1899:—

- EXPOSURE METER.**—No. 13,216. "An Improved Apparatus for Determining Exposures in Photographic Printing." E. E. CORNABY.
- CAMERAS.**—No. 13,300. "Improvements in Photographic Cameras." THE LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY, Limited, and W. E. MARTIN.
- CINEMATOGRAPHY.**—No. 13,369. "Improvements relating to Cinematograph Apparatus." E. E. BARTLETT.
- CINEMATOGRAPHY.**—No. 13,370. "Improvements relating to Cinematograph Apparatus." E. E. BARTLETT.
- STANDS.**—No. 13,391. "An Improvement applicable to Photographic Camera Stands." Complete specification. J. WILKINSON and A. WILKINSON.
- FINISHING PRINTS.**—No. 13,402. "Improved Method of 'Finishing' Photographic Prints." C. VANDYK.
- ANIMATED PHOTOGRAPHY.**—No. 13,421. "Improved Means for simultaneously Operating Animated Pictures and a Phonograph or Gramophone." Complete specification. E. MALKE.
- ANIMATED PHOTOGRAPHY.**—No. 13,422. "Improved Means for Illuminating Animated Pictures." Complete specification. E. MALKE.
- CAMERAS.**—No. 13,524. "Improvements in Photographic Cameras." A. H. RIETZSCHEL.
- COLOUR PHOTOGRAPHY.**—No. 13,568. "Pressure Plate for Photographic Dark Slides used in the 'Lippmann Process' of Colour Photography." A. W. PENROSE and W. GAMBLE.
- SHUTTERS.**—No. 13,648. "Improvements in Photographic Shutters." THE THORNTON-PICKARD MANUFACTURING COMPANY, Limited, and C. G. WOODHEAD.
- COLOUR PHOTOGRAPHY.**—No. 13,666. "Improvements in the Method of and Means for Producing Images in Complementary Colours, suitable also for Use in Taking, Projecting, Inspecting, Testing, or Combining Three-colour Photographs, Prints, or the like." G. SELLE.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
15.....	Croydon Camera Club .....	Excursion: Epping Forest. Leader, A. Willcocks.
17.....	South London .....	Exhibitions and Exhibitors. W. D. Welford.
18.....	Birmingham Photo. Society ..	Excursion: Tewkesbury and River Avon.
18.....	Gospel Oak .....	A Chat about Lenses. H. Billingsley.
18.....	Hackney .....	Carbon Demonstration. Autotype Co.
19.....	Croydon Camera Club .....	My Experiences with Kinematographs. Hector Maclean.
19.....	Oldham .....	Excursion: Dukeries. Leader, J. Chadwick.
19.....	Photographic Club .....	Discussion: The New Photographic Printing Papers.
19.....	West Surrey .....	Affiliation Lecture: Defects, and their Remedies. E. Dockree.
20.....	Manchester Amateur .....	Gum Bichromate. W. H. Machin.
22.....	Ashton-under-Lyne.....	Excursion: Moberley. Leader, Thos. Glazebrook.
22.....	Hackney .....	Excursion: Guy's Hospital (Interior). Leader, W. A. Ellington.
22.....	Manchester Amateur .....	Excursion: Alderley. Leader, Councillor G. H. B. Wheeler.
23.....	Oldham .....	Excursion: Chester. Leader, C. A. Hempstock.
2.....	South London .....	Excursion: Addington Park. Leader, F. Goddard.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 6.—Mr. H. C. Rapson in the chair.

Mr. R. CHILD BAYLEY referred to a discussion upon the merits of Agfa as an intensifier a few weeks back, when he believed there was some uncertainty about the results. He showed two negatives which had been developed and fixed both together in a combined bath, but slightly under-developed. He intensified one with agfa, and, beyond the fact that it took a quarter of an hour instead of three minutes, the result was satisfactory.

Mr. S. H. FRY examined the specimen and said that, if he had not been told that the resulting print of the intensified negative showed more contrast than before, he should rather have thought the fresh deposit a general one all over the plate.

Mr. A. MACKIE agreed that there was decided intensification, but with it considerable blocking up of the shadows.

Mr. A. HADDON said this was due to peculiarities of the emulsion. He found a considerable and granular deposit of silver in the rebate under a magnifier.

Mr. MACKIE said that he had a thin negative which wanted but a very slight increase of density, which was rather difficult to get. However, he had some Wellington's intensifier, of which he added a small quantity to an ortho. sulphite, and carbonate developer he was using. The increased density he got was just to his taste; but he noticed that the solution threw down a dense yellow deposit, similar to ferrous oxalate.

The discussion became one upon the merits of Wellington's method of intensification, and it was found that, while some succeeded with it, others noticed that its behaviour varied with different makes of plate and sometimes with different batches of the same make. Some plates did not seem to be amenable to its influence at all.

Mr. J. S. TEAPE showed some comparative examples of the method of reduction advocated by him at a previous meeting and involving the use of permanganate of potash and sulphuric acid. He had altered the formula first given, and now gave the stock solution as follows:—

Permanganate of potash .....	3 grains.
Sulphuric acid .....	30 minims.
Water .....	24 ounces.

This was diluted, for negatives, by an equal bulk of water, and no stain, first noticed, now resulted. He was in a position to repeat his claims for it as a reducer of the characteristics of persulphate of ammonium, viz., in its power of reducing excessive densities without affecting the lighter detail and halftones. The plates were divided in three strips, one showing the capabilities of the permanganate reducer, one those of persulphate, and the third the original unaltered negative. The action by the persulphate required only five minutes against twenty minutes for the permanganate, and this he placed to the credit of the latter, in that it was more under control for that reason. Mr. Teape also showed some trials he had made on gelatino-chloride prints with the permanganate reducer at a strength of one drachm of stock to two ounces of water. It would be found very valuable for this branch of work, he said, and was not, to his knowledge, equalled by other methods. It was curious too that, in one case at least, the delicate tones had been intensified while the denser parts had been reduced.

Mr. MACKIE referred to the bichromate and sulphuric acid reducer, which it will be remembered, has been commented upon before by Mr. Teape, and said that for some purposes it was very satisfactory. He also touched upon a method mentioned by Mr. Henderson, which he had used for the improvement of an under-developed negative. It was bleached with mercury, and subsequently treated with iodide of potassium, an excellent printing negative resulting.

Several reducers and intensifiers having now been named, further discussion turned upon the utility of these aids.

Mr. S. H. FRY spoke against them, as dodges of a misleading and unchievous nature, and as tending to reduce the practice of photography from high to a low level. He was sorry to see that even old photographers were much deceived as the excusable beginner.

A heated argument ensued as to the possibility, asserted on one side, of correcting for bad exposures by intensification or reduction, which was denied by partisans of the other side, who asserted that only errors of development could be corrected by such methods, although it might be possible to obtain less bad prints by their aid; but to argue that a badly exposed plate could ever be made to equal a correctly exposed plate was erroneous in the extreme.

Mr. FRY said he had found in business that it took six months to get a man out of the habit of relying upon dodging for his negatives, and to rely instead upon good exposure and good development.

Mr. W. D. WELFORD showed a combination negative made up of a foreground of one and a sky negative, and explained the means he took to make a satisfactory join in the reproduction. After development, the plate was washed, and the gas turned up, the light being allowed access to the part which marked the join. The light was then lowered, and the fresh exposure developed up to meet his requirements.

### PHOTOGRAPHIC CLUB.

JULY 5.—Mr. H. Snowden Ward in the chair.

Mr. F. A. BRIDGE showed some mounts stamped in decorative relief with the name of the photographer, which he had been asked to bring forward on behalf of Alexander Aguilon, of the house of Grimaud & Chartier, of Paris.

Mr. T. BEDDING gave a chat on the subject of "Binocular Vision and the Stereoscope."

Mr. FRANK HAES referred to the adjustments which some abnormal sight required, and alluded to a case of strabismus and difference of focus combined, which has been accommodated to the stereoscope by moving the lenses to the peculiar conditions.

Mr. CHARLES WALLIS said he had a great deal to do with field glasses, and was often asked which was the more powerful of two telescopes. He was quite able, by focussing the two separately on some object, and holding one in each eye, to determine this point, whereas other people failed, or had great difficulty in doing so, and he supposed that this was due to the muscular training of the eye to which the lecturer had referred.

**Sheffield Photographic Society.**—At the usual monthly meeting of the Society, held at their rooms in the Masonic Hall, Surrey-street, on Tuesday evening, Mr. J. Tomlinson (the President) occupied the chair, and Mr. SPARHAM CAMP gave a practical demonstration on the

### PLATINOTYPE-PRINTING PROCESS.

hot and cold development, rough and smooth papers, using both the Platotype Company's and the new Platona paper. The lecturer said it was necessary that the paper be kept free from damp, and to do this properly a tin tube must be provided to store the paper. Mr. Camp showed how the prints could be developed by floating on the cold developer. The hot bath gave slightly warmer tones than the cold bath, and development was quicker.

It was shown that warm tones could be got during development by adding a small quantity of a solution of bichloride of mercury to the developer. Mr. Camp then toned some prints with the uranium nitrate bath, and said prints might be obtained of any warm colour by this method. The bath was used hot, as it worked much quicker than when used cold. The lecturer alluded to the Packham method of toning, but preferred the uranium nitrate, as the Packham system was more of a staining than a toning process. Mr. Camp then showed how platinum prints could be controlled in development by using a developer partly composed of glycerine. He first rubbed the print over with pure glycerine, he then used a brush, and with a developer weakened with water he brushed the developer over the print, and the picture came up slowly and under control. By this method over-exposed prints might be saved and local development applied. Mr. Camp handed round the room a lot of fine pictures he had got on platinotype, which were much admired. The demonstrator claimed for this process a first place for photographic printing papers, as results were got which were absolutely permanent and most artistic. A very hearty vote of thanks was accorded Mr. Camp for his instructive and practical demonstration.

#### FORTHCOMING EXHIBITIONS.

1899.

- August ..... One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C.
- Sept. 22-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- „ 25-Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18-24 ..... Croydon Camera Club.
- „ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

### Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### LONG-RANGE PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—With regard to your comments on Mr. Dallmeyer's long-distance view of the Isle of Wight, may I point out that the island, instead of being twenty-two miles across the water, is only twelve from Boscombe. Twenty-two miles is about the distance of Newport and Caribroke, the high ground in the neighbourhood of which is, I believe, visible. Ten miles of the twenty-two are then overland.

From Bournemouth, thirteen and a half miles from the Needles, I have with a four-and-three-quarter-inch lens obtained a fairly good view. The high cliffs behind the Needles and a good portion of the coast-line are well defined, though the Needles themselves are not visible. On the negative the outline of the island is faintly visible almost as far as the mainland and also in the other direction towards St. Catherine's Point, the whole length of the image being about an inch and a half, and the high cliff at the Needles measuring about one-fortieth of an inch in height.

From Folkestone there is an opportunity for a much longer shot in the direction of the French coast, which is often clearly visible. This should be an excellent practice range for the tele-photo, the distance being twenty-three miles over water and inland objects some miles from the coast being often in sight. I should like to know if this has been attempted.

It has occurred to me that the summit of Snowdon should be an excellent station for obtaining long-distance views. You are here often above the mist, the buildings afford shelter from the wind; there is now a railway to carry up the apparatus, and there are possible ranges up to eighty miles. A view of the Isle of Man from Snowdon at a range of seventy-five miles would be a truly remarkable achievement!

Nearer London there must be plenty of opportunities of obtaining the

powers of the tele-photo at long ranges, but there seems to be very little done in this way. The South Downs afford plenty of good stations, and near the sea the atmosphere is often remarkably clear. A very accessible and little-frequented spot is the summit of Beachy Head. From here there are many suitable objects at considerable distance overland, and you are not likely to be disturbed by inquisitive visitors, even if you stop there all day. It is best reached from the Old Town, but a still day must be chosen, for there is absolutely no protection from the wind.

I am surprised that the possibility of securing exceptional views, that cannot otherwise be obtained, has not more strongly attracted enterprising photographers. In Wales there is a great opportunity of securing fine bold mountain views with the tele-photo lens, views that cannot be possibly secured with an ordinary lens, for the finest peaks only show their most striking outlines at distances of six or eight miles, or more.

In the case of Snowdon, the clearness of the atmosphere can only be ascertained by making an ascent, the state of the weather at the foot being a very uncertain guide as to the conditions prevailing at the summit, 2000 feet higher. I once made an ascent from the Pen-y-Gwryd side at one o'clock in the morning in heavy rain, the top being shrouded in mist, saw the finest sunrise and best view of the year, and descended to Beddgelert through another thick mist. September is perhaps the best month for a clear view, but it is often intensely cold at the summit. It was below 40° F. on the above occasion at the top, and about 70° at the foot of the mountain.

Those who are fond of climbing, and who have sporting tastes, should find long-range photography among mountains very attractive. Even if baffled by the weather, you have the pleasure of the climb, and are certainly no worse off than after a day's fishing without a bite, or a day's shooting without coming in range of anything worth powder and shot; and these are common experiences that every sportsman is willing to risk. Success may come but seldom, but, when it does arrive, you will be in possession of a photograph that is for the time unique, and that probably few others will succeed in acquiring. There is a sporting interest about tele-photography, quite apart from the scientific or pictorial value of the results.—I am, yours, &c., C. WELBORNE PIPER.

46, Shooter's Hill-road, Blackheath, S.E., July 10, 1899.

#### PHOTOGRAPHY IN DOTS.

To the EDITORS.

GENTLEMEN,—I beg to enclose you a couple of small specimens of two screen negatives showing a coarse and fine grain effect, though both are taken through the same screen. I also thank you for the editorial reply to Mr. Wheeler, and I may say that my screens are quite opaque in the grain, and, no doubt, could be used as process screens, as one of the prints would show, the dots in the shadows being quite clear. The enclosed, however, were not made on "process" plates, but, undoubtedly, would tell better when properly handled. I have been using the screen for view work out of doors, and have actually taken a snap-shot through one (quarter second).—I am, yours, &c., F. G. WILLATT.

101a, Fulham Palace-road, Hammersmith, London, W., July 10, 1899.

#### MACHINE PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I notice in your issue of to-day a query re machine photography. Your correspondent would get some information from Mr. Huson's little work on photogravure. The press he refers to is probably the "Arloff." If I could see my way clearly, I should like to try machine photogravure, as I have suitable premises and power and some knowledge of the matter, and, if your correspondent cares to communicate with me, I could make an appointment to discuss it with him.—I am, yours, &c., EUSTACE CALLAND.

Hillside, Putney-hill, July 9, 1899.

#### THE BLACK COLOUR OF THE RESIDUE IN ACETYLENE-GENERATORS AN INDICATION OF THE TEMPERATURE OBTAINED.

To the EDITORS.

GENTLEMEN,—Some time since I questioned the accuracy of a statement in yours—LANTERN RECORD—pointing out that such black colour is also an indication that bad carbide had been used. In proof of my statement, I forwarded a sample of black residue which I knew to be the result of bad carbide.

In yours of the 7th inst.—LANTERN RECORD—I am replied to that this sample has been submitted to Vivian B. Lewes, who states that it is a good example of the results of over-heating in the generator.

I have no hesitancy in repeating my original statement and adding that, instead of the black residue (sent sample) being due to over-heating,

it is the result of carbonaceous matter which was with the carbide at the time it was placed in the generator.

In proof of the accuracy of my statement and to question the answer of Professor Vivian B. Lewes, noted in yours of the 7th inst., I send per post herewith sample of carbide which has been in no generator, and will ask you or your correspondent, G. R. Baker, to give Professor Vivian B. Lewes the opportunity of passing this sample through any generator, and I have no doubt in anticipating the result will be a black residue, same as that on which he has expressed an opinion which I hold is not in accordance with the facts.

The proportion of this bad carbide per "drum" are matters that may follow, it is now sufficient to say, I hold it is unreasonably large—that, where it is present, users of carbide get a correspondingly small yield of acetylene and a black residue in generator, which black colour is not due to over-heating.—I am, yours, &c.,

J. V. ROBINSON.

Malahide.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. F. Mowll, 45, Hardman-street, Liverpool.—Two photographs of the Right Rev. J. C. Ryle, D.D.

F. W. Wells, Station-road, Paddock Wood.—Photograph of Brenchley Church. Two photographs of Canon Taylor. Photograph of group consisting of Canon Taylor and other gentlemen. Photograph of Canon Taylor, Dr. O'Donoghue, and Father Melia.

RECEIVED.—BERGER & CO.; CONSTANT READER; AJAX; R. FRANCIS; M. M. LAHIR; and many others. In our next.

C. H. CROSBY.—Many thanks. When we have a little leisure, we hope to peruse.

M. BARNARD.—We do not think the photograph could be restored, or that any photographer would attempt to do so. The photograph has been returned to you.

A. L.—Your complaint is, probably, well founded, as we have heard similar ones; but, as you will not attest your communication with your name and address, it cannot be inserted.

TAXATION OF VEHICLE.—R. C. P. If the vehicle is used exclusively for business purposes, it is exempt from taxation; but if it is used, if only occasionally, for other purposes, a tax must be paid upon it. Under the circumstances, we suspect the appeal will not be very successful.

TENANCY.—TENANT. If the three years' agreement ends in September next, you must vacate the premises, unless you renew the agreement to continue the tenancy. The landlord is not bound to serve you with a notice to quit. The tenancy simply terminates at the end of the term.

MOUNTING CARBON PICTURES.—T. BUSS asks the best medium with which to mount large carbon prints on rather thick paper?—Nothing is better than starch paste, made tolerably thick. The paste is best applied with a sponge, as it breaks up the starch better than a brush does when a large surface has to be coated.

BLOTTER-OFF PRINTS.—L. OSBORNE. 1. Albumen and collodio-chloride prints may be dried, under pressure, between blotting-paper without fear of their sticking; but not so with the gelatine P.O.P. papers, as your experience proves. 2. Get pure and inert blotting-paper or blotting boards. Both may be had from Messrs. Marion & Co., and other large houses.

HAND-CAMERA QUERY.—W. BERRY. We doubt if you will be very successful in developing the plates so as to get good negatives. Ordinary plates, exposed with an aperture of  $f/22$ , with a shutter working at the forty-fifth of a second, unless they are exposed in an exceptionally good light, must be expected to prove under-exposed. The developer tried will bring out as much detail as any we know.

USE OF STILL-PURE WATER writes: "I want some pure distilled water for making toning baths and other purposes; but I am told that, if I distil it myself, I require a licence from the Excise to use a still. As I only want it for distilling water, is this correct?"—Yes. A licence from the Excise is necessary to use a still for any purpose, even for distilling water. The cost, however, is not great, only ten shillings a year, we think, if it is not used for spirit.

DEVELOPING P.O.P.—G. BAILEY. The commercial gelatino-chloride printing-out papers are not specially prepared for development printing, though they may sometimes be used for the purpose. It is manifest that any paper that is to be developed must be more carefully handled during its manipulations, as regards light, than when it is printed out. The light that is permissible for examining the progress of printing in the latter case would be quite fatal in the former.

RESTORING PAPIER-MACHÉ ACCESSORIES.—FLASHLIGHT says: "I have several papier-maché accessories with portions damaged. Can you give a recipe for making pulp, so that I can restore them? Fallowfield, several years ago, gave a good recipe made of soft paper, flour, alum, and water, but I have forgotten the quantities."—The proportions need not be very exact, so long as there is sufficient flour-paste to make the compound adhesive. If, however, you write to Fallowfield, they will doubtless give you the precise quantities they recommended.

PATENT.—NERO says: "Some year or so ago I described to a friend an idea I had for an improved hand camera, and he thought much of it at the time. Since then I know he has been making a hand camera, and has applied for a patent for it, and the application has been granted. I have reason to believe it is the same as I described to him. If it is so, have I any remedy?"—Yes. Wait till the complete specification is published, and, if it is as you surmise, oppose the sealing of the patent on the ground that he obtained the invention from you. He will, doubtless, then be glad to make terms with you.

TESTING ALUM.—A. R. S. says: "Will you kindly test the alum herewith. After carefully searching out the cause of spots on prints herewith, we find that they first show themselves after coming out of alum bath. We had this alum from a chemist. I may say we have never had any spots like this through using other people's alum."—In reply: We do not undertake such matters as the testing of chemical compounds. If the alum is at fault, you had better reject it. In the event of your requiring an analysis, you had better address Mr. Thomas Bolas, of 60, Grove Park-terrace, Chiswick. Of course, you would have to pay a fee.

COLOURING PLATINUM PRINTS.—ALFRED FRISKE says: "Some few months ago I had occasion to put a scarlet coat on a platinum print, and it has gone dark. Can you tell me if there is anything between this colour and the print that does not agree? I have used the same colour on carbons years ago, and they remain quite good."—Evidently there is, but we do not know the composition of the colours that were employed. Vermilion is a sulphide of mercury, but we do not imagine that the platinum image pure and simple would have any effect upon that. The case may, however, be different if the paper contained any of the iron compound or the acid used to remove it.

LENS FOR HAND CAMERA.—T. BLAGDEN says: "I want a lens for a quarter-plate hand camera for a special purpose. It must have a working aperture of not less than  $f/5.6$  included, an angle of  $80^\circ$ , and give all objects beyond six feet microscopically defined, as the negatives will have to be enlarged six or eight diameters. The lens must be used with its full opening. Whose make do you recommend?"—It is against our rule to recommend any particular maker's goods. We may say, however, that the qualifications laid down are quite incompatible with each other. There is no lens in the market that will fulfil the conditions named, nor is there likely to be with our present knowledge of optics.

TRANSFERRING COLLODION FILM.—F. J. says: "Would you kindly inform me if it is possible to transfer a collodion film (negative) from the glass support on to canvas? If so, how to do it? I do not think it can be done, but I am told it is possible. I am well up in the wet-plate process, but never heard of the film being transferred on to canvas."—It is possible, with some practice, to transfer the film to canvas, primed as it is used by artists. It may be done in the following way: The glass plate upon which the picture is made is treated with French chalk or waxed; the canvas is given a coating of gelatine and allowed to dry. The picture, when dry, together with the canvas, are immersed in a thin solution of gelatine, and carefully squeezed together and allowed to dry. The picture can then be stripped off. As we have just intimated, some practice is necessary, particularly with large sizes, to ensure success.

LENS QUERY.—J. L. says: "I should take it as a favour if you could give me a little information. I have an old portrait lens without the back-glass, and would like to know whether I could get a back glass, also the likely cost of same. The front is of meniscus form, two glasses cemented together of about  $8\frac{1}{2}$  inches focus covering half plate to perfection. The mount has rack-and-pinion movement, but without stops, I have tried another lens in the back similar to the front, but can only get a picture 2 inches by 2 inches. Any information you can give me on the subject will be greatly appreciated!"—The maker of the lens will fit it with a suitable back combination. We cannot say the cost. As the front combination is  $8\frac{1}{2}$  inches focus, and the mount is not fitted with stops, we assume it is an antiquated quarter-plate portrait lens. If so, the cost of the back lens will be more than the instrument will be worth when completed. Second-hand quarter-plate lenses are only worth a few shillings each in the market.

STEREOSCOPIC NEGATIVES.—R. WARDEN writes: "1. I have an idea of going in for stereoscopic photography. I am undecided what size plate to adopt. The choice seems to be between the old  $6\frac{3}{4} \times 3\frac{1}{4}$  and the double quarter  $6\frac{3}{4} \times 4\frac{1}{4}$ , but I find that neither of these sizes are stocked at several dealers I have inquired of, of my favourite brand. If I get a camera of the  $6\frac{3}{4} \times 4\frac{1}{4}$  size, could I not use two quarter-plates, which are to be had anywhere, in it? 2. Is there any magazine stereoscopic camera on sale that will take two quarter-plates for stereoscopic work?"—In reply: 1. Yes; but there is the difficulty in developing two separate negatives to exactly the same density. This, however, is not a serious difficulty seeing that a trifling difference in the two halves of the picture is not very apparent when the finished result is seen in the stereoscope. 2. The only apparatus of the kind that we call to mind is that of N. Richard, of Paris—agents, Negretti & Zambra; but whether that takes plates of the standard English quarter-plate size we are not sure. We think not.

\* \* Owing to our absence at the Convention this week, many communications have had to be held over.

## EX CATHEDRA

THE Gloucester Convention is an event of the past. All the contributing circumstances operated to bring about a remarkable success. The charming weather, the beautiful scenic, historical, and architectural surroundings of which Gloucester is the centre, combined to give the Conventioners every chance of passing an enjoyable week in the practice of photography, for which it is safe to say they have not hitherto found such favourable opportunities. From the people of Gloucester, headed by the Mayor and Corporation, the greatest kindness and courtesy were experienced during the week, and to them the heartiest acknowledgments of the whole of the Convention are due. The thanks of the members which are recorded in our report of the proceedings elsewhere only faintly testify to the gratitude entertained for Mr. F. A. Bridge (Hon. Secretary); Mr. Dugdale (Local Hon. Secretary); and the other members of the Local Committee for the hard and ungrudging work they performed during the week, and thus, all round, the recollections of the Gloucester meeting of the Convention are of the happiest character.

ON Monday last the Select Committee of the House of Lords, charged with consideration of the Copyright Bill and Copyright (Artistic) Bill, held another sitting, Lord Monkswell presiding. Mr. Edward Cutler, Q.C., who has been deputed by the Board of Trade to make a report on the Artistic Copyright Bill, gave evidence regarding its various provisions. He pointed out that if they gave photographs, say of a picture, a shorter term of copyright than the term of the original picture—which was proposed in the Bill—they would come in conflict with the second article of the supplementary clauses of the Berne Convention. In other words, if they adhered to the proposal to give a shorter term to photographs in order to carry out the Berne Convention, they must give the foreigner a longer term than the native Briton. That would call forth considerable comment, and showed want of uniformity. With regard to the clause dealing with registration of works of art in order to secure copyright, he suggested an alteration bringing the clause into harmony with the clause requiring an assignment to be in writing.

\* \* \*

A CORRESPONDENT informs us that the Swiss Photographic Society have petitioned their Government to alter the Copyright Act of 1883, and what is more, they have every reason to believe that the Swiss law will be altered in their favour. "Petition: § 1. It is no longer necessary to register the photograph, but the photographer shall make a register containing all photographic negatives, indicating the date of taking, and this register shall be acknowledged by law for the whole time of the duration of protection. § 2. The duration of protection shall be thirty years, and begin on January 1 of the year in which the negative was taken."

\* \* \*

IN OUR News and Notes last week we gave an extract from the *American Journal of Photography*, in which Mr. Hahn suggests that some of its readers would do well to experiment with some of the old printing processes, so as to make them available by the light shed upon them by modern photography. In doing this the writer re-echoes what we have more than once advised. Some of these old processes, if experimented with, *plus* our modern knowledge of the chemistry of the subject, might, no doubt, be turned to profitable account; any how the results would be interesting, if

nothing more. The ferro-prussiate, or blue process, with its many modifications, which is now so largely used, was described by Sir John Herschell nearly sixty years ago. The platinotype, one of the most generally used processes of the present day, is closely allied to another old process of Herschell's. One of the processes described by Mr. Hahn is what was known as the Catalysotype process of Dr. Wood. Amongst these old processes were what were known as the "Chrysotyp," "Amphityp," "Chromatyp," "Ferrotyp," "Fluorotyp," "Energiatyp," &c. Some of these printing methods were sensitive enough for camera exposures. Most of these old processes are described, with formulæ and working details, in Hunt's *Manual of Photography*, which went through several editions in the "fifties," and which, though long since out of print, may often be met with at second-hand bookshops for a trifling sum. It is also to be found in most photographic libraries. Photographic societies are often hardly pressed for subjects, hence we again suggest the overhauling of some of these forgotten processes, with modern ideas upon them, as food for experiment and discussion.

\* \* \*

THE Oberammergau Passion Play has been frequently photographed. This year it has been cinematographed, and the results, through the enterprise of the Royal Aquarium management, are now being shown in the St. Stephen's Hall. Londoners now have the opportunity of seeing what this play is like without having to pay a visit next year to the highlands of Bavaria to see for themselves, and whether it is worth the journey, if for that purpose alone. We are told from Berlin that the Sultan has long had a passion for the cinematograph, and has now determined to turn it to practical use. He wishes to see, without the trouble of travelling, the working of the Anatolian Railway, and has given orders to a cinematograph specialist to prepare, regardless of cost, a series of pictures covering 1100 kilometres of the line. These pictures are to be shown to him, when done, in the Imperial Theatre at Yildiz Kiosk. This is rather a large order for the cinematographer, and we know some who would have liked to have had the job, particularly as it is to be done "regardless of cost."

\* \* \*

OUR readers will, doubtless, remember the hue and cry there was, on the part of artists and archaeologists, some time ago when it was first proposed to pull down the west front of Peterborough Cathedral, and to rebuild it, for the safety of the structure. As we pointed out at the time that there were plenty of photographs of it in existence that would show whether or not the architects had despoiled the building to the extent it was alleged they would by making the structure safe and stable. Since the work has been practically finished, we have heard little on the subject, so we may safely conclude that it has been done fairly to their satisfaction. Last Friday, in the presence of the Dean and the representatives of the Restoration Committee, the high cross on the southern gable—the crowning point of the completion of the principal restoration of the huge façade—was placed in position. The work of restoration has been in progress for about fifteen years, and has cost something like 80,000*l.*, which has principally been expended on ensuring the safety of the building. To most persons a fine cathedral presents a better appearance in a stable condition than it does in ruins, and, as we have just said, photographs of the west front taken now will show,

when compared with those taken before the "desecration was commenced, how much the original design has been de-parted from, if at all.

\* \* \*

A QUESTION was put in the House of Commons on Friday last as to whether Buckingham Palace, with its art treasures, could not be made available to the public? In reply thereto, Mr. Akers Douglas said that the objections to the opening of the Palace to the public were that it is unsuitable, from internal arrangements, for exhibition, and it is almost continually occupied by members of Her Majesty's family, adding that the Queen has given every possible facility to the public to view Windsor and other Royal palaces, and that he was not prepared to ask Her Majesty to make any concession in regard to Buckingham Palace. It is tolerably well known that the collection of paintings at Buckingham Palace is far better than that at Windsor, as the fine photographic reproductions of them by the houses of Hanfstaengl, of Munich, and Braun, of Dornach, testify. The Queen possesses some of the finest Vandyks in this country. By the way, speaking of pictures by Vandyk, we see, by the judgment delivered on Saturday in the case of the sale of some of the Peel heirlooms, that Mr. Justice Byrne directed the sale of two Vandyk pictures. It will be interesting to note who will be the purchaser of them, and, when sold, whether they will remain in this country. A large proportion of the old masters when they are sold here find their way ultimately abroad—frequently to America. Will it be so in this instance?

\* \* \*

WHILE on the subject of art matters, it may be mentioned that the Turner Exhibition at the Guildhall has closed its doors. In the few weeks it was opened it was visited by nearly 225,000 people. This shows how art is now appreciated even in the busy city of London. The Court of Common Council will shortly be asked to authorise the holding of another Art Exhibition next year, and there is little doubt that these loan exhibitions will be a fixed annual institution.

\* \* \*

A FINE-ART and Industrial Exhibition is announced to be opened in November next at Newark-on-Trent by the Duchess of Portland. The schedule of classes for exhibits includes a Section H, devoted to photography. Mr. Bliss, photographer, Newark, will forward full particulars to those interested upon application.

\* \* \*

It is a regrettable thing in connexion with photography that it can be used for persecution in so many ways. Last week we alluded to the way in which Madame Dreyfus was persecuted by the ubiquitous photographer and cinematographer, when visiting her unfortunate husband in the Rennes prison. Now it appears, according to the correspondent of the *Standard*, some enterprising photographers having been able to take, from the roof of a neighbouring house, snap-shots of the prisoner whilst walking in the garden, but this has now been covered in with a large awning in order to prevent further indiscretions—and very right too, say we. It will be remembered that, when this unfortunate man was first convicted of an offence of which most people out of France thought him not guilty, or at least not proved guilty of, and of which now a large majority in France believe him innocent, he was degraded in front of the

soldiers, and, after his stripes had been torn off, photographed. This photograph has since been shown publicly in London. At the time the sentence was passed and the photograph taken, we mentioned that it was the first time that photography had been used for such a purpose of degradation, and we now hope, for the credit of the art, it will be the last, when applied to such purposes.

\* \* \*

AMONG the visitors to the Gloucester Convention was Mr. F. Dundas Todd, the editor of the *Photo Beacon* (Chicago), who, after an absence of seven years in America, has returned to Britain for a brief holiday, which we trust will be a pleasant one. Mr. Todd tells us that American Conventions are conducted far more spiritedly than our own, and that great features are made of the elements of professional photography and manufacturing interests at those gatherings. Notwithstanding these drawbacks (if drawbacks they are), we believe that Mr. Todd, on his return to the States, will be able to tell his American brethren that the British Convention could hardly be excelled in point of enjoyment and good fellowship.

\* \* \*

AT Rome next year the principal photographic society purposes holding an International Exhibition on lines similar to those upon which the recent successful Exhibition at Florence was conducted. It will be recollected that at the latter Exhibition an Invitation Section of British pictorial photography was one of the features most appreciated by the visitors. It is proposed to repeat the experiment at Rome, and invitations will shortly be issued to the principal exhibitors.

### TONING TROUBLES.

WHAT Mr. Burton aptly describes as the battle of the toning baths still occupies the arena, and from reports received of the proceedings of the various photographic societies, and numerous queries and letters from our correspondents, it is abundantly evident that the subject of toning, whether with platinum or gold, still presents many difficulties and uncertainties. A few months ago we dealt exhaustively with the subject of toning baths, contrasting the ancient with the modern methods employed, and pointed out the causes which rendered changes necessary, and which made the older forms of toning unsuitable for the new and modern papers. A few further words confined to the causes of failure with modern makes of commercial papers might prove instructive to the large number who still meet with occasional difficulties and failure. As we previously pointed out, the principal difference between the albumenised or salted papers of the past and the gelatino-chloride of the present day consists in the comparatively small quantity of silver chloride and of silver nitrate in the uncombined state which exists in the latter as compared with the former. Again, there is the difference that the old papers were salted and sensitised by floating on a solution, whilst the modern papers are surface-coated with an emulsion consisting of silver chloride and an organic salt of silver instead of the free nitrate.

First, let us consider how gold acts upon the reduced silver in the print. It is, perhaps, as well to point out that the chloride of gold of commerce should properly be called auric acid, since its formula is  $\text{AuCl}_3\text{HCl}$ , or, more properly,  $\text{HAuCl}_4$ , by which it will be seen that for each atom of gold deposited upon the print three atoms of chlorine are set free, and in its

nascent condition unites with three atoms of the reduced silver of the printed image, reconverts it into silver chloride, and thus, in a large measure, undoing what the light has done. To prevent this, the addition of some salt, the acid of which is capable of being easily displaced by chlorine, is necessary. Hence the function of soda acetate, phosphate, or tungstate as employed in ordinary toning baths, is, first, to neutralise the  $\text{HCl}$  molecule of the gold chloride; and, second, to absorb or combine with the liberated chlorine as the gold is deposited, thus preventing, in a great measure, the bleaching of the print.

It will be familiar to most photographic printers that with most of these baths the orthodox method was to mix at least twelve hours before using. The reason for this was because the  $\text{HCl}$  molecule of the auric acid is not immediately displaced by a neutral solution of an acetate or phosphate requiring some hours for completion. By carefully neutralising with a solution of carbonate of soda previous to mixing, however, this time was saved, and an acetate or other similar toning bath might be used at once. This method of toning was satisfactory with albumenised papers of all kinds, and with collodio-chloride or matt papers; but, with the advent of gelatine as a vehicle for containing the emulsion for surfacing the paper, fresh and new troubles were introduced. Old and tried formulæ refused to act. Either the prints would not tone at all, or toned very unevenly. Usually the fainter half-tones and lighter-printed portions toned rapidly to a cold blue, whilst the deep shadows remained red, and the so-called double toning took place.

We invariably hold as a maxim that, when the cause of any trouble is clearly understood, the remedy is obvious and the difficulty disappears. In this case the reason is of a twofold character. That this may be clearly understood, let us examine the action of gold chloride on gelatine. If we dissolve a few grains of gelatine in water, say, in a test tube, and add a few drops of the stock solution of gold chloride, the gelatine is at once gelatinised and becomes insoluble. Again, take a strip of dried gelatine and immerse in a solution of gold chloride, and no amount of after-washing will remove the gold, nor will boiling water dissolve the gelatine. The two have entered into some form of chemical combination, and an absolutely insoluble product is the result, just as if an excess of formalin had been added. It is easy to see, then, that with a gold-chloride toning bath and a gelatine-surface print this combination will take place over the whole surface of the print, and the toning bath be robbed of its gold. Another factor of a different kind also comes into force, and is even more the cause of double tones than the one we have referred to. In albumenised papers the sensitising salt was usually the free nitrate of silver, with citric or other organic acid as a preservative. This, being soluble in water, was easily eliminated in the washing previous to toning; but in gelatine papers the whole of the silver nitrate is converted into the nearly insoluble organic salts of silver such as citrate or tartrate, and this, being intimately bound up within the gelatine of the film, is almost impossible of removal by washing. Returning now to another reaction of gold chloride, that upon salts of silver. If we take a solution of auric chloride and add to it carefully an exact equivalent of silver nitrate, we obtain a precipitate consisting of a mixture of aurous and argentic chloride. Two of the three atoms of chlorine go to form silver chloride, and the gold is reduced to the insoluble aurous state, or  $\text{AuCl}$ . This aurous chloride is exceedingly unstable, and easily suffers reduction to the metallic state, consequently toning takes place rapidly

to the blue stage; but for reasons which we will now point out this is a decided disadvantage.

As was previously stated, the unexposed paper consists of a uniform and homogeneous mixture of silver chloride and silver citrate, or other organic salt; but, when exposed and fully printed, this condition no longer exists. As the printing of the image progresses, the chlorine eliminated by the action of light from the silver chloride unites with the organic silver salt, to form further amount of silver chloride, which is itself again darkened, and so on until the necessary depth and vigour is obtained. It will be readily seen, therefore, that in the fully printed proof the whole of the free salt of silver may be used up in the deepest shadows, whilst the half-tones and lighter tints still contain a considerable quantity, and the whites the whole amount originally in the paper. If, now, this silver salt is not removed, or is insufficiently removed, and a toning bath containing gold chloride be employed, the above reaction at once takes place, as precisely the same change takes place in the gold, whether organic or nitrate of silver be used. The gold chloride of the toning bath is precipitated as silver aurous chloride, not only on the partially printed portions, but in still larger quantities over the white or unexposed parts, whilst the shadows, which really require the most, receive the least. At the same time, the toning bath is robbed of its gold, and rapidly becomes useless. The deduction from these facts is obvious: First, gold chloride is unsuitable for toning gelatine prints; and, second, we see the necessity of taking adequate measures for the total removal of the organic salts of silver previous to placing in the toning bath.

The first of these objects is satisfactorily attained by the use of gold sulphocyanide instead of the chloride. When gold chloride in solution is added to ammonium sulphocyanide solution, a deep red precipitate is first formed of gold sulphocyanide, and ammonium chloride remains in solution. On the application of a gentle heat this precipitate dissolves first as a red and then a colourless solution. This gold solution no longer combines with gelatine, and will mix freely with a solution of it without any apparent disturbance taking place.

The second object is attained by a preliminary bath of salt and water, which converts the whole of the citrate and tartrate into chloride of silver. A further wash in one or two changes of water now removes the resulting soda citrate or tartrate, and uniform, even toning is the result. The double salt of hyposulphite of soda and gold may be substituted for the corresponding sulphocyanide salt, and is, in fact, the active toning agent in what is termed the combined bath. But space forbids to go further into the subject at present. On this latter point we may have something to say at a future date.

**Cloud Photographs.**—Photographs of clouds have a use beyond that of serving as adjuncts to cloudless negatives of land or seascape subjects, as may be seen by a reference to the *Monthly Weather Review* for February last, in which there is to be found a set of photographs taken by Mr. Alfred J. Henry, of the United States Weather Bureau. Naturally, when a photographer takes a cloud picture, it is usually for the purpose referred to by us; but, in these particular photographs, when the camera has once been set to work, the operator is not content with a pretty picture, he takes a series of successive pictures, thus obtaining data of the production, alterations, and dissipations of clouds of a particular class. Then, again, by virtue of previous arrangements, the same clouds can be

photographed from other stations at considerable distances apart, and thus negatives can be secured of the same masses of clouds from different standpoints.

**Novel Use for the Kinematograph.**—Reports are given of a very remarkable use to which the kinematograph has been put before a select assembly in the University of Kiel, there being present the Prince of Monaco, Professor Von Esmarch, the famous surgeon, and numerous professors, doctors, and medical students. M. Doyen, who had charge of the experiments, explained that it was not possible verbally to describe the performance of an experiment in such a manner as to make it impossible to avoid error in carrying it out by one who had not actually seen it performed. M. Doyen, by means of certain alterations in the kinematograph, has been able to make a perfect series of pictures of various kinds of operations, from the first cut of the knife to the putting on of the bandages. Every phase of the operations was thrown on the screen with marvellous accuracy. M. Doyen insists that his invention will be of incalculable benefit to students of surgery. He received an ovation from the medical students who witnessed the experiment.

**Stereoscopic Röntgen Rays.**—At the Royal Society's second, or Ladies', *Conversazione* were several exhibits of interest to photographers, among them an arrangement by Mackenzie Davidson for giving a stereoscopic effect in X-ray investigation. Under ordinary conditions, as is well known, the effect produced is merely like a "shadow on the blind," a foreign object being shown apparently on the same plane as objects in front of or behind it. Mr. Davidson so arranges a rapidly rotating disc, with two apertures cut in it, and so rotates it, that each eye only receives the rays from the source of light opposite to itself, and never receives them at exactly the same moment that the other eye is receiving its rays. In the same way a Röntgen-ray image cast on the fluorescent screen is only seen by one eye and the image cast by the other source of light is only visible to the other eye. If these succeed one another fast enough, faster than ten times a second, the impressions are naturally apparently continuous owing to the effect of "persistence of vision," and thus the two images will coalesce as in a stereoscope.

**Diffraction Gratings and Colour Photographs.**—Another exhibit of great interest was that of Mr. R. W. Wood (whose method of colour photography was explained in our issue of July 7) and exhibited by Professor C. Vernon Boys, F.R.S. It included a silvered photographic grating. The grating shown was on silver, and one of 2000 lines to an inch was a contact print on albumen, which was afterwards silvered and polished while wet. The spectrum obtained by its aid is of great brilliancy. There was shown a diffraction colour photograph produced in the manner described in the article referred to.

**The New Electrolytic Interrupter.**—Mr. A. Campbell Swinton, at the *Conversazione*, showed experiments with various electrolytic contact-breakers. Mr. J. W. Swan, F.R.S., showed effects produced by the action of modifications of the Wehnelt-Coldwell mercury interrupter. An article by Mr. Campbell Swinton appears in *Nature* of July 7, describing a modification of the latter instrument, which now appears to be brought to a state of absolute perfection and will, where electric current of high potential is available, almost revolutionise work with the intensity coil and Crookes tube. The new break has several points of advantage over the original design. It can be used with alternating currents equally well as with continuous; it does not appear to be liable to "fatigue;" and it is capable of a simple and easy control over the ampérage and frequency of the break, while still being of so simple a design that any one at all conversant with laboratory work could with ease construct one himself without calling in the aid of an expert.

## PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

GLOUCESTER MEETING, JULY 10-15.

At the Tuesday evening meeting the following paper was read by the author:—

### SOME FUNDAMENTAL POINTS CONCERNING DEVELOPMENT

In a preliminary paper on "Development," read before the Convention last year, I gave an abstract of the position of the question at that time, and in particular pointed out that the definition of a perfect negative given by Hurter & Driffield could not be accepted, because, in the first place, experienced photographers are aware that a negative that gives the best possible results with one printing process does not necessarily give the best possible result with every other process; and, in the second place, the assumption that a perfect negative must in its different parts transmit quantities of light proportional to the quantities of light reflected from those portions of the object that the particular parts represent involves a further assumption that the effect on the printing paper is directly proportional to the amount of light acting. This latter assumption probably holds good, within certain limits, in the case of enlarging on bromide paper, or in other printing processes in which the action of light causes no appreciable change in colour. It does not, however, hold good, and, on the face of it, could not be expected to hold good, in direct-printing processes where the action of the light at once begins to alter the absorption coefficient and other properties of the sensitive material.

In order to make clear the object of the, unfortunately, comparatively few experiments that I am now in a position to describe, it is necessary to recapitulate a little ancient photographic history. Until the publication of Hurter & Driffield's first paper, photographers generally held the belief that it is possible to modify the general character of a negative, especially the gradations, by altering the mode of development and the composition of the developer, and thus, to some extent, to compensate for errors in exposure and more particularly for over-exposure. This belief had gradually been developed as a result of the observations and experience of a large number of photographers, who for many years had made experiments and recorded their results, although in most cases they had not, it is true, tried to express their results in very definite figures. Now, I, for one, must confess to holding somewhat strongly the view that, when certain general conclusions have been arrived at as the accumulated experience of the practical workers in any branch of applied science or art, any contrary conclusions that may be deduced from the results of laboratory experiments should be examined very critically before being enunciated, and should be enunciated with considerable reserve.

In their first paper Hurter & Driffield arrived at two main results as the outcome of that part of their work that dealt with development. The first was that the character of a negative is determined by exposure, and not by development, and that the ratios of the densities or opacities is not affected by the mode of development. The second was that the ratio of the opacities remains the same at each stage of development, and that the only control that the photographer is able to exert on the printing quality of a negative lies in the length of time during which development is allowed to continue.

At the time of the last Convention, a second and lengthy paper, communicated by Hurter & Driffield to the Royal Photographic Society, was in process of publication, and every one who has read this paper will recognise that it materially changes the position in which the matter was left by their first paper.

The most important result in the second paper is that Hurter & Driffield, whilst they still regard exposure and not development as the main factor in determining the character of a negative, and whilst they regard the constancy of the density ratios as the fundamental point in quantitative photography, nevertheless, as the result of their later experiments, arrive at the conclusion "that, if all possible variations in concentration and in composition of developing solutions are to be taken into consideration, the density ratios of the visible image cannot be said to be constant."

They describe in detail, with diagrams and numerical results, experiments on the influence of variations in the proportions of pyrogallol, sodium carbonate, and potassium bromide respectively in the ordinary pyro-soda developer, on what they term the "inertia" of the plate. The practical significance of saying that the inertia is increased is that the result is the same as if the plate had been a slower one or had

received less exposure. Conversely, if it is said that the inertia is reduced, the meaning is that the resulting negative is the same as it would have been if the plate had been a quicker one or had received more exposure. To put it in another way, to increase the apparent inertia of the plate by modifying the developer is practically the same thing as correcting over-exposure, whilst to reduce the apparent inertia of the plate in the same sort of way is the same thing as correcting under-exposure.

Now, Hurter & Driffield find that, by increasing the proportion of pyrogallol, the sodium carbonate remaining constant, the inertia can be increased more than twice, or, from the practical point of view, more than twice. The proper exposure can be corrected in this way. The effect of increasing the pyro is higher when the proportion of sodium carbonate is low (25 parts of the crystallised carbonate in 1000) than when it is high (100 parts of the crystallised carbonate in 1000 of developer).

They also find that, by increasing the proportion of potassium bromide up to 8 parts in 1000 in the ferrous-oxalate developer, the inertia of the plates can be increased as much as thirteen times, or in the pyro-soda developer as much as eleven times; or, stating it practically, that more than ten times the proper exposure can be corrected by this means alone.

They state, it is true, that these differences disappear if the development of the plate is allowed to reach its limit, that is, is allowed to go on until the whole of the effect of light has been developed out, and are apparent only when development is stopped before this limit is reached. It is obvious, however, that, when a photographer is endeavouring to correct for over-exposure, his object is to prevent the whole of the light effect from being developed, and to stop development before the limit is reached is therefore exactly what he is aiming at.

Further, Hurter & Driffield find that an increase in the proportion of sodium carbonate reduces the inertia of the plate, that is, corrects for under-exposure, but the effect is relatively smaller than the effect in the opposite direction of increasing the proportion of pyrogallol or potassium bromide. In other words, the power of correcting for under-exposure is considerably less than that of correcting for over-exposure.

It will be seen at once that Hurter & Driffield's second paper may fairly be said to bring us back to where we were before, and to afford numerical justification for the older beliefs of practical photographers. It is impossible to avoid feeling regret that their earlier somewhat sweeping conclusions as to the absence of any control during development for errors of exposures should have been enunciated at all until their investigations had covered a wider range of variations in the composition of the developer. Even as it is, their second paper does not entirely cover the limits within which a photographer has power to make variations, and does, in fact, make variations in extreme cases.

Since Hurter & Driffield, so far as control in development is concerned, to a large extent contradict their first paper, and bring us back very much to the old conditions, it might seem that there was nothing further to be done. However, as the old beliefs have been disturbed, and various questions have been raised, it seems very desirable that the same field of observation and experiment should be traversed by some other observer.

There is also another consideration which, from the practical point of view, seems to me to be very important. In their second paper Hurter and Driffield state that the error of speed determinations by the methods described in their first paper may be as much as twenty-five or thirty per cent. Some years ago, in the course of the discussion on a paper of mine at the Royal Photographic Society, two of the most experienced photographers then living stated that they did not think it was possible to recognise in the negative and resulting print a difference of twenty-five per cent. in the exposure under ordinary working conditions.

From the practical point of view, differences that cannot be recognised by careful inspection may fairly be regarded as of little importance; from a scientific point of view they may be very significant.

From the practical point of view it seems to me to be sufficient to adopt a method of working that does not require a photometer, and is in other respects comparatively simple. All that is needed is a scale composed of bands of graduated opacities, such as may be produced by the old method of exposing different strips of one and the same plate for different lengths of time, and then developing it. This scale is then used for subsequent experiments, plates being exposed behind it in the ordinary way. After exposure the exposed plate is cut into two or four strips, and each strip is developed in a different way. In order to compare the fixed and dried strips they are simply placed together in their original positions, and examined against a sheet of white paper or other uniformly illuminated

surface. If no differences can be detected in this way, or if the differences seem to be merely differences in general opacity, the strips should next be put into a printing frame, with a sheet of some chosen printing paper behind, and in this way a direct comparison of their printing quality can be made.

With regard to the point at which development should be stopped, in the case of the negatives ordinary working conditions should be imitated as far as possible, and therefore, in most of the experiments to which I shall refer, the plan adopted was to stop development as soon as a given strip of the scale, representing shadow detail, had become distinctly visible.

In the case of prints, we may stop either when two successive bands on the scale, representing shadow detail, have become equally dark, or when a certain band at the other end of the scale, representing high-light detail, just becomes visible.

Operating in this way, it is comparatively easy to demonstrate that the general belief as to the effects of altering the proportions of pyrogallol and of alkali respectively is correct, and that Hurter & Driffield's conclusions on these points are also correct. In the case of bromide, it is quite easy to demonstrate the marked effect on the negative, and with a new developer, adurol, it is even easier than with pyro. It is also not difficult to demonstrate the marked differences between the negatives produced by pyrogallol and metol respectively, especially in the early stages of development, and also to demonstrate the equally important fact that these differences tend to disappear when development is allowed to proceed to its limit.

The present position consequently may be briefly stated as follows: With a given exposure, a photographer has control over the character of his negative in two ways: firstly, by varying the proportions of the constituents of his developer in accordance with the general belief resulting from accumulated experience; and, secondly, by selecting his developer, the results with metol and pyrogallol, for example, being markedly different.

Another point to which I have given some attention is that investigated by Mr. Watkins, namely, whether there is a constant ratio between the time required for development and that which elapses between the pouring of the developer over the plate and the first appearance of the image. The experiments are not yet complete, but, so far as I have gone at present, I am able to confirm Mr. Watkins' main conclusions within certain rather important limits. Where the exposure has been fairly accurate, or where we are dealing with line subjects or similar classes of work, the method seems to have very considerable utility. Where, however, there has been any considerable excess of exposure, my experiments up to the present lead me to the conclusion that the old method of inspection of the negative during development is the only safe one, and that development by time passes beyond its proper limits. So far as detail in the shadows is concerned, the different negatives do not show any marked difference when the developing factor is employed, but I find that at the other end of the scale there is a marked loss of detail in the high lights, the different bands of the scale tending to become indistinguishable from one another in all cases where the exposure has not been so great as to bring about incipient reversal.

At present I am inclined to the view that it is impracticable to reduce development to a matter of figures; the operator must watch the progress of the process if he wants to get particular results. Development, in fact, is an art.

C. H. BOTHAMLEY.

#### ANNUAL MEETING.

THE Annual General Meeting and election of the new Council was held at the Guildhall, on Wednesday morning. The President (Mr. W. Crooke) occupied the chair, and there were about twenty-five members present. The election of the Council resulted as follows:—

Harold Baker, Birmingham.	H. M. Hastings, London.
W. Barry, Hull.	A. Horsley Hinton, London.
R. Child Bayley, London.	W. Hodges, Gloucester.
Thomas Bedding, London.	E. J. Humphery, London.
Godfrey Bingley, Leeds.	Sydney Keith, London.
C. H. Bothamley, Weston-super-Mare.	C. Phipps Lucas, London.
Dr. Oscar W. Clark, Gloucester.	Percy Lund, Bradford.
Alexander Cowan, London.	J. L. Lyell, London.
H. S. Crump, Gloucester.	Major Lysaght, Chichester.
T. B. Dallmeyer, London.	George Mason, Glasgow.
Dr. P. H. Emerson, Lowestoft.	H. Medland, Gloucester.
A. Haddon, London.	J. Porritt, Leicester.
Martin J. Harding, Shrewsbury.	Ralph Robinson, Redhill.
	H. P. Robinson, Tunbridge Wells.

J. C. Ruthven, Dublin.  
A. Seaman, Chesterfield.  
W. Taylor, Leicester.  
Alexander Tate, Belfast.  
J. Stuart, Glasgow.  
E. J. Wall, London.  
J. H. Walker, Leeds.

H. Snowden Ward, London.  
S. B. Webber, London.  
G. Watmough Webster, Chester.  
W. D. Welford, London.  
J. B. B. Wellington, Elstree.  
A. Werner, Dublin.

Messrs. H. Harvey George (Great Yarmouth), William Goodwin (Glasgow), and B. W. Dugdale (Gloucester) are *ex-officio* members of the Council for one, two, and three years respectively.

Mr. F. A. Bridge introduced the subject of alterations or additions to certain rules, which were agreed to as follows:—"That if a member elected on the Council has not paid his annual subscription (5s.) before August 1, his seat on the Council shall be vacant." "That the election of Hon. Secretary shall take place at the first Council meeting held in London after the Convention." It was also resolved that past presidents (vice-presidents) shall be *ex-officio* members of the Council.

With reference to next year's meeting of the Convention, it was unanimously decided to accept the Newcastle and Northern Counties Photographic Association's invitation to meet at Newcastle.

Messrs. Fall and Fry were appointed Auditors.

On the motion of Mr. Bridge, a hearty vote of thanks was accorded to Mr. Dugdale (Hon. Secretary) and the Local Committee of the Gloucestershire Photographic Society for the enthusiasm they had displayed and for the efficiency and assiduity with which they had carried out the arrangements for the Convention. Mr. Dugdale and Mr. Medland briefly acknowledged the vote.

After the meeting the members adjourned to the Spa Cricket Field where the official Convention group was taken by Mr. A. H. Pitcher.

In the afternoon a visit was paid to the Cathedral, where the members were met by the Dean, who conducted them over the building, and gave an account of some of the more important historical and archaeological features of this ancient structure. Subsequently Mr. F. W. Waller (architect to the Cathedral) dealt with the architectural side of the building. At the conclusion of the tour the President, on behalf of the Convention, accorded a vote of thanks to Dr. Spence and to Mr. Waller for their services as guides.

After lunch a cricket match was played between sides representing the Gloucester Conventioneers and the United Kingdom Conventioneers.

The following was the score:—

MR. WALWIN'S ELEVEN.		MR. WELFORD'S ELEVEN.	
Mr. Clarke, c. A. H. Ward, b. Welford	1	Mr. Burton, b. Walwin	7
Mr. W. Walwin, b. Welford	2	Mr. Alf. Werner, c. Dugdale, b. Trohman	8
Mr. F. A. Trohman, b. A. H. Ward	3	Mr. Appleby, b. Walwin	2
Mr. Dugdale, junr., b. Welford	12	Mr. A. H. Ward, b. Walwin	9
Mr. E. A. Ind, c. Appleby, b. Welford	4	Mr. W. D. Welford, not out	13
Mr. Walwin, junr., b. Welford	0	Mr. H. H. Ward, c. Bedding, b. Trohman	0
Mr. H. V. Hyde, b. Welford	0	Mr. W. W. Naunton, b. Trohman	4
Mr. W. J. Crowl, not out	8	Mr. Gandy, c. & b. Walwin	1
Mr. Thos. Bedding, b. A. H. Ward	4	Mr. Wallis, c. Hyde, b. Walwin	9
Mr. R. E. Beard, c. Wallis, b. Welford	2	Mr. E. J. Humphery, b. Hyde	2
Mr. Emery, b. A. H. Ward	6	Mr. J. H. Avery, b. Walwin	3
Extras	6	Extras	6
	47		50

At the Council Meeting subsequently held Mr. Thomas Bedding, F.R.P.S., was unanimously chosen as the next President. There was a discussion on hotel arrangements, and it was decided that in future there should be no official headquarters, but that a list of hotels should be supplied, from which members were to make their own choice.

#### ANNUAL DINNER.

The Annual Dinner was held at the Bell Hotel in the evening. The President (Mr. W. Crooke) occupied the chair, and was supported at the chief table by the Mayor and Mayoress (Alderman and Mrs. Braine), the City High Sheriff (Councillor Hatton), the Town Clerk and Mrs. Blake-way, Mr. M. H. Medland (Chairman of the Local Executive Committee), Dr. Oscar W. Clark and Dr. Campbell. The company numbered about 120. The loyal toast being duly honoured.

The President proposed "Success to the Photographic Convention of the United Kingdom." The first meeting of the Convention was held at Derby in 1886, since which time it had grown, it had given pleasure and instruction, and spread interest throughout the kingdom. The members travelled nowhere but where they left their mark, or rather took it away with them; and, though their particular calling assisted them to take away a great portion of the cities they visited, the proportion was so small, and the damage done so little, that he did not think it could be

called very harmful. At one time it was considered that the Photographic Convention should be an educational organization, and many members urged the importance of having as many scientific papers as possible read. Personally, however, he did not consider that the members of the photographic profession, amateur and professional, were in a frame of mind during the Convention week to digest many scientific papers. His opinion was that they would never make the Convention anything but a gigantic picnic. They might have one or two papers during the week, but they had such a multiplicity of photographic societies throughout the country that the members must be positively gorged with photographic intelligence by the time they came to the Convention. With the toast he coupled the names of the General Hon. Secretary and Treasurer of the Convention, and the Local Secretary.

In reply, Mr. Bridge acknowledged the very great help which he had received from the members of the Local Committee, and especially alluded to the valuable assistance which Mr. Dugdale had rendered.

Mr. Dugdale said he had been only too pleased to do what he could to make the Gloucester meeting of the Convention a success. He was standing before them as the local Hon. Secretary, who, in accordance with the traditions of the Convention, would be laid out at the end of the week as an "unfixed print;" but the Gloucestershire Society numbered amongst its members three doctors, and he hoped with their assistance to be able to stand the racket of the work and be still above ground when the Convention was over. Mr. Dugdale paid a tribute to the indefatigable energies of the Local Committee, to whom great credit was due, and said they had been greatly aided in their efforts by the valuable co-operation of the Mayor, City High Sheriff, and Town Clerk.

The President announced the receipt of messages from absent friends. Mr. John Stuart, the ex-President, wired from Moffat: "An old friend of the Convention wishes you and all Conventioners a good night and many returns." Mr. A. L. Henderson wired: "I am with you in spirit and join in toast, 'Vive la Convention.'" Mr. Child Bayley, writing from his bed in Gloucester Infirmary, thanked the members for their kindly expressed sympathy with him in his accident.

Mr. Bothamley, who gave the next toast, "Prosperity to the city of Gloucester," said they had all of them, at least, they said they had attended all the meetings of the Convention except one, but he doubted whether those who could carry their minds back to the many successful meetings they had had could remember any place in which they had been more cordially received than in the ancient city of Gloucester. Members, of course, tried at times, at any rate if they had any time during the Convention, to pick up some of the characteristics of the places which they visited, and the first impression that he formed about the city of Gloucester was as to its extraordinary greediness. He had no sooner turned out on Saturday morning with a camera and the rest of it than he was stopped by a kind of brigand with a rectangular box covered with new paint and fresh varnish, and having a rectangular slit in the middle, and he was asked to give something to the waifs and strays. At the moment he was studying in vain a map of the city, and, as he did not know where he was, he explained that he was astray himself, and that he had better keep his money, which he did. But that particular greediness of Gloucester was rendered very obvious by the way in which it had managed to secure for itself a great many of the best things, and it was only mitigated by the great readiness of the Gloucester people to share all those good things with the members of the Convention. With the toast he coupled the names of the Mayor, City High Sheriff, and the Town Clerk. If he might trespass once in a way, he thought it was a particularly gratifying fact to find that all the "brain" of which they had official cognisance was divided between the people of Gloucester and the members of the Convention.

The Mayor, in his reply, said that Mr. Bothamley anticipated the desires of the good citizens of Gloucester when he wished prosperity to their fair city. On behalf of those citizens he thanked Mr. Bothamley and the members of the Convention generally for their hearty good wishes. Gloucester, as they all knew, was no mean city, and, although perhaps it was not very large, comparatively speaking, it was of considerable importance. They had heard from Mr. Bothamley that he had been much interested by all that he had seen in Gloucester, even the collection boxes which were placed under his nose upon his entering the city. He was sorry Mr. Bothamley did not subscribe his mite, because he might have been doing something to assist some of the waifs and strays in the cities to which some of the Conventioners belonged; for he could assure him that they had no waifs and strays in the prosperous city of Gloucester. He felt highly honoured that the visit of the Convention had been made during his mayoralty, and he had done all he possibly

could to accord the members a very hearty welcome. He trusted that the snap-shots and interesting visits which they had made during their stay in the city and neighbourhood would result in increased prosperity to the old city.

The Sheriff and the Town Clerk also replied.

Mr. S. B. Webber, in giving "The Photographic Press," said that one of the leading members of that body, who was no longer with them, had much to do with the institution of the Convention. With the toast were coupled the names of Mr. Thomas Bedding (editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*), Mr. E. J. Wall (editor *Photographic News*), and Mr. F. Dundas Todd (editor of the *Photo Beacon*, Chicago), each of whom responded.

The latter gentleman expressed himself as highly delighted with the civic welcome which had been accorded the Conventioners, and concluded by saying he was authorised to convey the good feeling of the National Convention of America to the National Convention in Britain.

Mr. Medland, in proposing the health of "The President of the Photographic Convention of the United Kingdom," eulogised the services which Mr. Crooke had rendered, and said the citizens of Gloucester, and particularly those belonging to the local photographic society, would always look upon that week's proceedings as one of the important events in their lives.

The President, replying to the toast, which was accorded musical honours, announced that the Newcastle meeting would be presided over by Mr. Thomas Bedding. Proceeding to speak of the high attainments which were possible in photography, Mr. Crooke said there was a multiplicity of workers in the ordinary sort of thing, and the grievance was that the public seemed to be absolutely and perfectly satisfied with the ordinary thing. In that matter education was necessary, they wanted to bring the public up to the standard of appreciating the higher forms of art and more artistic productions.

Mr. Percy Lund submitted "The Ladies, and the Convention ladies in particular," coupled with the name of Mrs. Mason, who appropriately replied.

During the evening songs were sung by Miss Hargreaves, Mr. Vivian Hyde, Mr. Bridge, Mr. Debenham, and the President, while Mr. Welford contributed a selection on the one-string fiddle. Mr. W. H. Morgan and Mr. Bridge shared the accompaniments. The proceedings terminated with the singing of "Auld Lang Syne," Mrs. Mason sustaining the solo part, and of "God Save the Queen."

The members had an enjoyable excursion on Thursday, about 130 of them visiting Chepstow, Tintern, and Symonds Yat. On Friday morning about 100 members left Westgate Bridge aboard the steamer *Avonmore*, which conveyed them to Ashleworth, Deerhurst, and Tewkesbury.

The meeting at the Guildhall on Friday evening was largely attended. The following papers were read:—

#### BINOCULAR VISION AND THE STEREOSCOPE.

WRITERS on optics frequently institute a comparison between the human eye and the photographic camera, or, strictly speaking, the photographic lens and camera, which are supposed to be alike in their capacity for forming real images of objects situated in front of them. This comparison, if briefly examined, will take us a little on the way towards realising what binocular vision is.

The manner in which a photographic lens forms an image is, of course, well known. When we photograph either a near or a distant object, there has to be a movement of the focussing screen, or, in optical language, an alteration of the conjugate foci. Let us examine in what manner the eye forms an image on its focussing screen, otherwise the retina. In so doing, we need only consider that portion of the eye which is termed the crystalline lens. This acts precisely in the same way in the formation of the retinal image as does the photographic lens in the formation of the image on the ground glass of the camera. This crystalline lens may, for our purpose, be described as a double convex lens of unequal radii of curvature. It is, in fact a crossed lens, which forms images of near and distant objects in virtue of what is termed accommodation. Accommodation consists simply of the ability of the eye to alter its radii of curvature at will. The crystalline lens is held in position between two sets of muscles called the ciliary muscles, and when the eye is directed towards some near object it becomes more convex in virtue of the property which these muscles have of compressing the lens, thus shortening its anterior radius, and, of course, increasing its degree of curvature. On the other hand, when the eye is directed towards some distant object, the curves of the crystalline lens are flattened, and their radii consequently increased.

What I have so far said may bring home to us the exact amount of resemblance there is between the eye and the photographic lens as image-forming systems. In the case of the photographic lens used for the formation of images of near or distant objects, a movement of part of the optical system is necessitated, whereas with the human eye the same end is simply fulfilled by its ability to alter its curvatures at will.

In this connexion it is, perhaps, permissible to speculate that it would be a very great advance in photographic lens construction if the optician of the future could provide us with a lens of some plastic transparent material which, by a little pressure one way or the other, would give us an instrument convertible to either a long or short-focus lens at will. Whether it is too much to expect I do not know, but in these days of advancing enlightenment scarcely any speculation as to what remains for achievement by scientific agency seems too far-reaching.

Now so far we have dealt only with monocular vision—that is, vision with the single eye. But in nature we have to deal with two eyes, and consequently we must consider in what manner those eyes, which project on a plane surface plane images of objects situated in front of them, yet enable us to realise the marvellous phenomena of distance, depth, height, and solidity—binocular vision, in short.

Lecturers and writers on the subject of stereoscopy usually tell us that we see two dissimilar views of an object or scene which the brain combines, thus giving us the effects I have just enumerated. But, if we go deeper into the theory of binocular vision, we shall see that there are revealed to us some very beautiful principles underlying the functions of the eye in the conveyance of the representation of solid objects to the brain.

Let me, therefore, briefly recount portions of the theories of several eminent men on this question of binocular vision. Helmholtz, perhaps the greatest writer we have had on this subject, points out that the eyes only see one object at a time, while Brewster, another celebrated writer on binocular vision, tells us that the eyes are always in motion, and that they realise distance, depth, and solidity by what is commonly called the greater or less convergence of the optic axes. This term is susceptible of a simple explanation. You may imagine two right lines drawn in front of the eyes, and that these lines either parallelise for distant objects or converge for near objects. The greater the convergence, the greater the amount of stereoscopic relief; the greater the parallelism, the less the relief.

Wheatstone, the inventor of the reflecting stereoscope, presents a slightly different theory. He says, in effect, that binocular vision is a psychical function—in other words, it is produced by the mental fusion of two dissimilar views.

Brücke, a German author, relies for an explanation of the theory upon the controlling action of the ciliary muscles upon the crystalline lens, to which I have already referred. Thus we obtain three distinct theories—the muscular, the mental, and the optic axes.

But the late Professor Tyndall expounded a theory which will appeal, I think, to most of us as perhaps the most easily comprehensible and rational. He asserts that, "when the optic axes are converged upon a certain point of an object, the other points produce a certain determinate effect on the retina, and are in some measure the objects of our attention. There is thus established an association between a certain convergence of the optic axes and certain incidental impressions, and this association may, I think, be so refined by habit as to enable us to infer the solidity of a body or the relative distances of objects, while the optic axes are kept immovably fixed on a single point."

In all probability the theory presenting the greatest subtlety and difficulty of acceptance is that advanced by an American writer—Dr. Le Conte. He says that "the retinal image impresses the retina in a different way; this impression is then conveyed by the optic nerve to the brain and determines changes there, definite in proportion to the distinctness of the retinal image, and then the brain or the mind refers or projects this impression outward into space as an external image, the sign and facsimile of an image which produces it."

Having briefly endeavoured to place before you some of the various known theories of binocular vision, I will digress from the main subject, and point out the importance of the theory of binocular vision in relation to what we call pictorial photography, a relation which is not widely suspected, and may strike many with surprise.

About ten years ago a notable book was produced under the title of "Naturalistic Photography." Like other notable books it excited much comment and opposition, and, above all, was grossly misunderstood. Most people, however, are probably unaware that the whole theory of naturalistic photography which the author, Dr. Emerson, worked out, relies entirely upon an intimate study of the phenomena of binocular

vision. In the third chapter of this work, mostly overlooked by its reviewers, the author goes very fully and exhaustively into the principles of binocular vision—what the eye sees, and how it sees it, and, reasoning out the application of those principles to photography, comes to the conclusion that we should go to nature for our photographs and photograph nature as the eye sees it, that is, in accordance with the laws of binocular vision.

You will recollect that Helmholtz told us that we only see one object sharply or distinctly at a time, and that we are only conscious of the other and surrounding objects. This proposition, I take it, no photographer who uses his eyes will controvert, and thus it will be perceived that naturalistic photography, as reasoned out by Dr. Emerson, relies entirely on a scientifically established basis.

This association of science with art may, perhaps, have the effect on many that the red rag is popularly supposed to have on the bull. No one likes less to hear of the intimate relations of science with art than the "photo-faker" or "photo-dodger." Still the fact remains that, in making pictorial photographs, you have here a little bit of sound scientific reasoning which places you secure in the knowledge that, if you take your photographs according to these rules, you are producing them just as the eye sees nature, which seems to be only a common-sense way of doing things.

Passing now from this branch of our subject, we come to the stereoscope itself, of which a body of photographers like that which I am addressing needs no description. Among the general public, however, the functions of the refracting stereoscope, dismissing from our minds the form which depends upon reflection, are woefully misunderstood. It does not possess any wonderful occult property, nor is it a magic construction that produces effects difficult of explanation. The functions of the stereoscope may be summed up in the remark that it resembles a pair of spectacles in so far as it assists or corrects the human vision in the examination of binocular photographs. It has often occurred to me that the stereoscope as an optical instrument receives but scant justice at the hands of modern opticians. I feel that, when one wishes to view photographs by the stereoscope, he should have his eyes tested as carefully as he should for a pair of spectacles, as it is obvious that defective vision enters as much into the one case as the other. Were this systematically carried out by competent persons, it might be possible to put the lenticular stereoscope on a footing from which it would not easily be disturbed. Each instrument would be fitted for the special optical requirements of the individual, inequality of foci, distance of eye separation, and the aberrations being provided for. The fact that this is not done is probably the cause of so many of the complaints that we hear from people who do not understand what stereoscopic photographs are, or how they are viewed, and for whose defects of vision, where they exist, no provision is made. Thus a beautiful branch of photography is very often misunderstood and condemned.

But my main purpose now is to speak, not about the improvement of the stereoscope as an optical instrument, but to endeavour to throw out a few suggestions for means whereby you can dispense altogether with the stereoscope in the examination of binocular photographs.

In times gone by, several methods have been published, designed to enable persons of normal vision—and it is of normal vision only to which I refer throughout—to see stereoscopic pictures stereoscopically without a stereoscope. It is one of the easiest things in the world to acquire, and, when acquired, it is a faculty from which you can extract a world of enjoyment.

Going back to Brücke's theory, by which the ciliary muscles of the eye are supposed to play the most important part in binocular vision, there is a simple system, devised some thirty years ago or more, which, if practised for a little while, will give the eyes the necessary command over axial parallelism, divergence or convergence, so as to enable them at the focus of normal vision to see stereoscopic photographs in relief.

Here it is. Two sheets of white paper are required. Upon one, near its upper margin, make two circular marks in ink an inch apart; upon the other one, also a circular ink mark or dot. Hold the latter paper about 20 inches from the eyes; interpose the former about midway between the eyes and the paper with the one dot, so that the three dots appear in a line. Now look intently at the farther dot; the mind will shortly see three dots on the first paper. When this effect has been obtained, substitute for the paper with the two dots another sheet having dots  $1\frac{1}{2}$  inches apart, and, when with these the effect above described has been obtained, the distance of separation may be yet further increased, and the muscular control thus obtained will enable a binocular photograph to be substituted for the sheet of paper with the two ink dots. The centres of the photographs should be not more than  $1\frac{1}{2}$  inches apart, and these may be

MEMBERS OF THE FOURTEENTH ANNUAL PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM

Negative by A. H. Pitcher, Photographer, Gloucester.

gradually increased. Let these two photographs and the dot be looked at as were the three dots. Three photographs in a row will shortly be seen, and then the beautiful effect of a single photograph in relief will present itself. In all my experience of photography, nothing has given me so much fascination as the moment when, having practised the little experiment above described, I first acquired this valuable facility of dispensing with the use of a stereoscope. It is one of the greatest pleasures I enjoy that I am always able to take up a slide or transparency and instantly and perfectly perceive it in its stereoscopic form.

So far I have explained how this little feat, which is wrongly supposed to be difficult of acquisition, but is not, may be acquired; but I would now wish to draw your attention to the fact of the human eyes being, after all, probably the best stereoscopes to employ, having been recognised by Elliott, the Edinburgh optician, over sixty years ago, before the invention of the stereoscope itself, either as a reflecting or refracting instrument.

The first stereoscope (Elliott's) contained no lenses or prisms at all. It consisted simply of a plain apparatus for enabling you to see stereoscopically dissimilar drawings, which, of course, long preceded the advent of stereoscopic photographs.

Imagine, then, a rectangular box, about eight inches long, with a division running down its centre, and two holes where the latter-day lenses are fixed, and a groove at the further end wherein you drop your specially prepared drawing or stereoscopic photograph. These holes themselves may be supposed to perform the function of the stereoscope in parallelising the optic axes. They enable the left eye to see the left picture and the right eye to see the right picture only, and this is practically all that is required in the examination of binocular photographs.

Ordinarily we converge the optic axes, but what we have to do in stereoscopic photography is by muscular effort either to parallelise or diverge them, and so present one picture to the left eye and another to the right eye.

I hope it will not be imagined that the suggestion I am about to make is too chimerical, but it occurred to me recently, noticing that books are being illustrated by means of stereoscopic pictures, that children—in whom one might imagine the muscles of the eye to be in a supple state—might be easily taught, without inconvenience, to use their eyes as a stereoscope in the manner I have above already described.

I have recently tried the experiment, with every success, upon two of my own children, who are in the habit of looking at stereoscopic photographs in a stereoscope. I constructed a box similar to the one described by Elliott, put prints in, and told them what to look for and how to look for it, and after a while they could see binocular photographs quite stereoscopically without the use of lenses. I then took a Holmes-pattern stereoscope and removed the prisms, and still the children were able to obtain the stereoscopic effect. Hence it will be seen we here go to the first principles of Elliott. It seems to me that, in this age of physical and muscular education, which is largely taking the place of mental culture, somebody might take up this point of the education of the eye for stereoscopic purposes. By so doing it is not difficult to foresee the time when the majority of our books would be illustrated by stereoscopic photographs, and we should all be able without effort to see reproductions of art and nature in the relief, depth, and solidity with which the eye sees creation itself.

I hope to refer to this subject on future occasions.

THOMAS BEDDING.

#### "WORDSWORTH'S COUNTRY—ILLUSTRATED BY THE PHOTOGRAPHER."

In the north-west of England lies a tract of rugged hilly country, measuring some thirty miles from north to south, and about twenty from east to west. Among these northern hills, some of which rise sufficiently high to be justifiably called mountains, lie some of the most beautiful vales in our island, and in many of these valleys delightful lakes are imprisoned. There is probably no other tract of country in Europe where, within a comparatively small area, one may find so many types of scenery or enjoy such varied atmospheric effects.

Although most of the principal valleys converge towards the highest group of mountains, from whence the observer can see them stretched out, map-like below him, radiating outward like the spokes of a wheel, yet each of these valleys has a character of its own, "in some instances," says a well-known writer, "as if they had been formed in studied contrast to each other, and in others with the united pleasing differences and resemblances of a sisterly rivalry."

The forms of the mountains also are endlessly diversified, and their slopes change in condition, as the altitude becomes greater, from meadows of great fertility to wooded steepes, and then to rocky ridges, precipices, and screes, with summits often made up of huge blocks of stone scattered in the utmost confusion. Streams and cataracts fall down their sides, which often, after heavy rain, increase in number and volume, and fill the air with a strange roaring sound.

In winter the hill tops carry a snow cap for several months; in summer their sides become green with bracken, and all kinds of ferns and mosses flourish in the rock crevices with the greatest profusion.

I have said that the valleys show great diversity of appearance. Some of them are well under cultivation, others remain stony and wild, serving only to provide pasturage for the flocks of mountain sheep. Woods abound in places, oaks, beeches, birches, and the mountain-ash flourishing to the greatest extent. As to the lakes themselves, they differ very materially one from another, some being broad and having irregular shores, others narrow and resembling a wide, winding river, some covering an area of many square miles, while a more numerous class are but a few acres in extent.

Such, then, is a very bald and inadequate description of the main features of our English Lake District. One need hardly add that for the sun-artist in particular, also for any who occupy themselves with the study of nature in its varied phases, the Lake Country possesses the most alluring fascinations and the most advantageous opportunities.

But it enjoys also, in addition to natural charms, the interest of association with many writers and poets, who have lived or sojourned among its hills, and left in prose or verse lasting records of the impressions they experienced under the influence of external nature—impressions of storms and sunrises, of mysteries of light and atmosphere, of the songs of birds and the plashing of streams.

Southey, Coleridge, De Quincey, and, last but not least, Wordsworth, are a few of the names indissolubly connected with the Lake District.

William Wordsworth interpreted nature as no poet had done before his time, and, as he lived almost the whole of his life in the Lake Country, there is hardly a feature which he has not in some way touched upon, hardly a beautiful scene which has not received at his pen

"The gleam,  
The light that never was on sea or land,  
The consecration and the poet's dream."

His poetry is the poetry of common things, of human experience connected with nature's works, of nature as the connecting link between the human and the Divine.

Believing that to study the poems of Wordsworth in the midst of those rare natural surroundings which inspired them would be at once the best way of finding the truths they hold, and arriving at a full appreciation of the country we call Wordsworth's, I began not long ago, at those times which I could spare from a busy life, such a course of work. Visiting first one valley and then another, I followed the footsteps of the poet from his school days at Hawkshead to the home of his old age at Rydal, seeking, under the guidance of his verses,

"To look upon the hills with tenderness  
And make dear friendships with the streams and groves."

But that was not the whole of my scheme. Mental impressions were to be aided with pictures. With my camera I proposed to make records of Wordsworth's favourite haunts—his homes, and hoped even to represent pictorially some of the finer descriptive passages that lent themselves best to such treatment.

The scheme was ambitious—an attempt to grasp the connexion between nature, art, and poetry, and so far but a small measure of progress has been achieved.

To be quite candid, the pupil was far from apt; getting and spending had put him out of tune with the subtler side of nature. Like a child plunged suddenly amid unfamiliar wonders, he was distracted by the sensuous beauty of the scenery, the joy of basking in glorious sunshine, the delights of climbing lofty crags, or of contemplating the wreathing mists as they unfolded the hills. All these things induced a condition of subjectively, rather than objectively, making personal action not unlike the paralysed moments of a dream.

Let me take you in imagination to the vales and mountains of Westmoreland and Cumberland, and, as we see the views upon the screen, I will venture to give a very brief epitome of Wordsworth's life, and adorn my tale with a few quotations from his poems.

PERCY LUND.

## TALES OF A WAYSIDE INN.

"Ticket for Gloucester, sir?" said the booking clerk at Paddington as he espied me through his little pigeon-hole window with my patent-rising, back-sliding, take-'em-any-how, brand new camera, with aluminium bayonet tripod.

The surprise on the man's face gave way to a grin and a wink as I corrected him and said, "Tourist for Cheltenham *via* Gloucester, please, where I may perhaps break my journey." As the change was handed to me I felt a calm satisfaction not so much at the fact that I had saved a few shakels of silver, but at the thought that I was stealing a slight march on the astute Conventioners by getting an extra half-day at Cheltenham and Oxford on my return if I wished to do so, a tip that future Conventionists to the Cider City and neighbourhood would do well to bear in mind.

It was close on seven in the evening of the Convention Dinner when the New Inn was reached; and I only got a hurried glance at the surroundings before dressing for the forthcoming gastronomic function about to be perpetrated at the Bell, which was the headquarters of the Convention, so that the description of the more ancient Hostel will have to wait until the "aching void" within is filled.

Being a stranger the forethought of kind friends provided me with a seat near the Beddington corner of the table (I dare say you know that corner, sir?) and after a cordial handshake with the future President I glanced around at the hundred odd guests there assembled, and requested my right-hand neighbour to inform me who were the principal persons present. He said he did not know them all, but gave me a few of the names hereinafter mentioned.

These names included two gentlemen in glittering armour—beg pardon—chains, whom I believe to be the City Lord High Executioner, commonly called the City High Sheriff, and the Lord High City Mayor (is that the correct title, sir?). Between these two were seated the Shepherd (President) of the Flock, a man without a crook; close by him sat the City's High Town Clerk and his partner, and the Society's high-minded local Secretary, next again was the Treasurer and Secretary of the P.C.U.K., Goodman Old Bridge, Esq. Other notabilities were Bishop (of London) and Lady Singwell, the G.O.M. and his son Ralph Redwill, Alphabet Leighotham, Esq., F.I.C., F.C.S., &c., Professor Murus (the sage of Cecil Court and patenter of "Anti-squint"), Percy Wordsworth, Esq. (*et ux.*), T. P. Shutter, Esq. (specially released for the occasion by Father Time), Keadck Dot of New York, U.S.A., Vyvison Jekyll, Esq., Philmand Plato (of Warwick), Herr Secco (of Berlin), Coalblack Fryers, Esq. (no relation to "Checky" of that ilk), Avery Carmel, Esq., Sandy Henderson, Esq., Harold Handsome, Esq. (of Brum), Albert Moredon, Tut Tut, Esq. (of Shaftesbury Avenue) the newly appointed Honorary Carpenter and Handy Job-master to the Convention, Harri Corniescen, Esq. (of Falmouth), Wantmore Paxcard, Esq. (of Chester), Walter Singlestrung Welldone, Esq. (of Chancery-lane or thereabouts), A. Fatman, Esq., Mrs. Fatman and the little Fatmen (accompanied by the Cathedral Belles), Snowdon Fairface, Esq. and Mrs. Fairface, Genial Alfred of Steepletown (*et ux.*). The Attorney General of St. Martin-in-the-Fields, and many others, including Lord Knowswho.

There was, however, one great link missing in the chain of illustrious names above mentioned; it was, alas! that of the Child of Photography, whose misfortune and sufferings were the subject of sympathetic comment throughout the evening.

The dinner, *per se*, was not an unqualified success. The cooking was good, but the difficulty we experienced at our table was to get served with anything.

By the way, I wonder how the word "waiter" became applied to the modern "*garçon*." I must look that up. If a "waiter" is a person who "waits," it is certain that at our table he "waited." We did not object to his waiting; it was the time he waited. He waited too long, and so did we; in fact, we are, I believe, still waiting for those absent courses. If one asked for calves' head, should he be given gooseberry tart?

One old waiting-man—we nicknamed him "Methuselah"—I at first mistook for the late Duke of Wellington. He was rushing about with a single plate in his hand, offering it to everybody in a most bewildering manner for about five minutes by the local "Waterbury." I thought the poor old chap had gone mad, and was about to ask his way to the local lunatic asylum, and end his days where the rattle of plates and dishes and the popping of corks would have to be carefully concealed from him for fear of exciting the suicidal mania that appeared to lurk in the corner of his feverish eyes.

The golden ambrosial fluid of France (uniced) was running like water, eyes were beginning to brighten, tongues to wag, or, as the editorial

loquacitor (good word that, sir) would have remarked, "The leashes of free speech are let loose upon us—let it be done." And it was done.

The Presidential Crooke rapped upon the table, and the bleating of his flock became silent even to the hush of expectancy. The speeches began. As the great pendulum of the Photographic Press will, doubtless, swing to and fro, marking with each beat the more minute details of these speeches on the page of time, it behoves me not, as a looker-on, to make many notes thereon. But what did strike me was the cordial harmony of the meeting. It was what one might term a Mutual Admiration Society.

The cordiality of the speeches of the civic and municipal representatives of Single and Double Gloucester, and the return of the courtesy by the President of the Convention was very marked. Then there were delicate compliments to the Press, coupled, Mr. Editor, with the name of the President-Elect, and the *apropos*-ness of his reply, seizing as he did in a masterly manner the points made by the President, and neatly turning them into humorosities of the first water, inspired perhaps in a slight degree by second and tertiary applications of the sparkling fermentations from France. Well-punctuated and mellifluous periods of peroration fell, sir, as they properly should do from the lips of the representatives of the Press. Some one again said, "Let it be done well" (with the accent on the "well"), and it was done, and done well, and had it been Donemore it might have been too dry. Speeches, toasts, and songs went hand in hand, and when at length the meeting broke up everybody was happy, a few hungry, and the majority—thirsty.

This meeting was but the precursor of another and less formal, though not less merry, one, for the majority of us adjourned to that ancient and delightful hostel yept the New Inn.

For those of your "perusers," Mr. Editor, who have not visited this Convention a little description of the *locus in quo* would not perhaps be considered out of place here.

The exact date of the erection of the New Inn is not recorded in local history, but it was rebuilt after a fire in the year 1457. Its architectural characteristics have been brought to light and enhanced considerably by its present owner and our host, Mr. Berry, of whom I shall have to say a word or two anon. This galleried inn with its trailing creepers and quaintly carved oak, so picturesque in the twilight, became at night a modern "All of 'Armony." It seems to me almost a sacrilege to say so. The courtyard was pleasant and cool after the heated dining-hall of the Bell, and tables and chairs were brought out, big and little groups formed, and conversation, song, story, and gaiety reigned supreme.

As I sat in a quiet corner I pictured the more stirring days seen in this quaint old country courtyard. What tales could not those black old beams unfold had they but the power of speech? and what a contrast there was between the scenes here in the days of old and the modern *café chantant* show before me. The booted and spurred gallant had given place to—the camera man. Such is the progress of civilisation!

The contrast was deepened at that moment by the clamour of the Cathedral chimes,

"Whose slow and stately changes,  
Speaking of bygone ages,"

made the chords of the piano sound like a jangle of profanity.

Generation after generation passes away, but those sonorous bells ring on and on, heedless of the flight of time—'twas a strange thought to think to the clinking of glasses.

Speeches were made, healths drunk, and the songs and music were alternated with clever card tricks by Mr. Wantmore Paxcard, and many stories told—all fit for publication, Mr. Editor—at least, until the ladies left at midnight, after which time it is not distinctly remembered who made the last speech or told the last story. All I know, sir, is that your very good health, with musical honours, ended a very enjoyable evening (and morning).

We retired to bed (after having partaken of light supper) to sleep "and perchance to dream."

I had a short dream; it caused me a little uneasiness, but it was only momentary.

I dreamt that the duck I had partaken of at dinner had gobbled up all the peas, and was floating on a pond, the confines whereof were bounded on one side by my diaphragm.

Mr. Editor, this and another story I may tell you some day—with your kind permission—is copyright, and if Professor Murus sneaks them for the next Convention there will be a vacancy on the staff of the paper he so ably conducts, and I shall have great pleasure in contributing to the

funeral expenses in the interest of humanity, even if I have to do a tight-rope performance afterwards.

On the next day (Thursday) a vast array of photographic apparatus was lugged and tugged and hugged by a perspiring multitude of enthusiastic ladies and gentlemen in variegated costumes to the railway station *en route* for the Chepstow and Tintern excursion.

At Chepstow they photographed the castle, the door of the courtyard, the keep, and, when they had nothing else to take, they took each other, and one gentleman, I am sure, was taking more than was good for him (his name is Nemesis). The best view I got was at the Beaufort at Tintern. It was a grand view, everything composed beautifully. Many others appreciated this particular view very highly, and it did not belie our first impression, for we all enjoyed it. I refer, sir, to the view of the luncheon tables.

Have you ever pulled from Tintern to Chepstow in a boat, sir? I have reason to believe, "from information received," that you have, and that your adventures were worth recording. I did hear that Professor Murus pulled stroke, and with lightning rapidity saved the ship, and that, in the language of binocular vision, your party not only saw "rocks" in the photographic sense, but felt the solid image thereof, and nearly landed, as Mr. Meter would have said, "in the middle of next week." This, in consequence of the Aethmatical Foghorn who steered you through the rapids slipping his rudder-string at the critical moment. I congratulate you all, sir, on your escape, and the Professor on the promptness with which he handled his oar. Truly, as the poet forgot to sing,

"In the hands of men entirely great  
The oar is mightier than the pen."

That night was a night of rejoicing, but all retired early in view of the morrow's excursion by boat through "Churchland," *via* Ashleworth and Deerhurst, to Tewkesbury. Stereoscopic Alfred, of Steepleton, photographed us on the boat just before starting, and forty or fifty other people wasted good material in a similar manner; but, I suppose, the one is for business and the other for the sake of reminiscence. I took—"Bass."

The river journey was pleasant, but business was brisk. The unconventional uncommercial travellers unbosomed the virtues of their wares indiscriminately; there was no escape for the victim except by drowning. I drowned my sorrow in another Bass, whilst some idiot drowned me with the contents of a ginger-beer bottle, the cork of which took a heavenly direction before its time. I would have burnt that cork slowly and surely with agonising torture had there been a fire, but as there wasn't I could not drown it, the only other means of death on board, and who ever heard of drowning a cork?

*En route*, every architectural subject was subjected to the searching glare of the lens.

As I don't, as a rule, care for churches (Sundays, of course, excepted), I took a stroll *solus*, alone, by myself, everybody else going to church—it is the proper thing, you know, sir—and I took a snap with a camera, specially filled for me by the amiable Moredun Allet (Sh! spell 'em backwards), at a bent old man with a sickle, standing on a rustic bridge near an old cottage, cutting nettles. There was a tall tree close by, and in the distance the church spire peeping through the tall elms, and some palings in the foreground; but, of course, I apologise to the Convention for thinking of taking such a rustic subject when there was a church in the vicinity. At Deerhurst, Harri Cornisson and I drove some sheep down a lane, and we never got near the church, and have no regrets. Some people do prefer lamb and mutton to bricks and mortar; it is human nature, except perhaps for a lanternist.

Here the passengers were cinematographed, and, had I not been at lunch at the time, I should have quarrelled with the boatman on the plank and disappeared into the waters beneath for the sake of a little variety for the cinematographist.

Tewkesbury is too well known to need comment, and the side alleys were particularly worthy of photographic effort. Life in the country slums contrasts very favourably with that of the greater cities.

This night is indelibly printed on the tablets of my memory. First, sir, your lecture, and Professor Murus's remarks on the question of the stereo squint, combined with another gentleman's views into futurity can never be forgotten, and the comical question put to you, sir, by the Chairman, when he asked you how it was he could sometimes see two images with his eyes when, in reality, there was only one? This reminded me of the story of two celebrated statesmen entering the House of Commons after dinner. One said to the other, "I say, Pitt, I can't see th' Speaker!" Pitt replied, "That's funny; I can see two!"

Not that I would insinuate for a moment that your Chairman was suffering from too much clearing solution, of which soda forms an integral part.

But the greatest fun of the night was meeting the commercial stranger from Scotland in the landlord's sanctum at the New Inn.

Sitting quietly in a corner, his bright eyes ever and anon twinkling with amusement at the witticisms of the President and others, his bulky form at length arose, and he held forth in a strain that you, sir, as well as those present, will never forget. His description of the photographer was quaint. He said, in his own inimitable Scotch way, that he "had often seen gentlemen—good-looking young gentlemen like the one opposite" (pointing to the Lord High Carpenter, whose waxed moustache had caught his lynx eye), "nicely dressed young gentlemen, some with knickerbockers on, and some with a round piece of glass stuck in one of their eyes—carrying what he thought was a small box." He had often wondered, he said, what these small boxes were; he didn't know what they called them, nor what they were for, but, as the fellows always carried a funny kind of three-legged pole with them, he presumed they were gentlemen bird-catchers in a good way of business.

Print fails to convey the humorous way this was spoken, but it went home to the flock amid shrieks of laughter. Being invited to attend the next Convention, he said he would be delighted to do so, did business permit; and there was one thing he would propose if he became one of the Society. He would suggest that the qualification of membership should be a double one, and that no member be allowed to attend Convention without a lady. If, he said, it needed two of those little boxes, why, let there be two, and one little three-legged pole, if they were expensive, as some one suggested, why, the same could be used by both.

As you, sir, very properly asked, Was blood relationship to guide the qualification of the lady members? The gentleman's reply was as emphatic to the contrary as the laughter was loud.

As the light was good, I took a snap-shot before retiring to rest. Good morning, sir.

Before closing, I cannot refrain from paying a high tribute to the kindness and attention we all received at the hands of the landlord and his amiable spouse, to say nothing of the pleasure we felt in having the company of his charming little daughter and baby. The President, as is well known, took a very fatherly interest in the latter. We were more than comfortable, and the staff ably assisted the landlord's efforts. The New Inn is the best hostel I have had the pleasure of visiting.

A GLOUCESTER PILGRIM.

## A STRANGER AT THE CONVENTION.

BY A SCOTSMAN.

It is said that opium exerts a powerful influence on the imbibers of the fumes of that said article, and, once indulged, the victim is practically powerless to escape from its snares; the same fascination—but, let us hope, in a beneficial instead of a hurtful capacity—obtains fast hold on the photographer who has once indulged in the delights of the Convention. He or she, or rather, to give that preference to the ladies which we learned as boys, especially when a flogging or some nauseous medical prescription was in question—she, or he, is with difficulty prevented attending, every effort is made to secure attendance at the annual pow-wow, or, more properly, photographer's picnic, and, when personal attendance is denied, the unfortunate Conventioneer is present in the spirit.

Your readers may pardon a few notes from one who was at Gloucester—a stranger in a strange land—who, from his very ignorance, may perchance write something that if not edifying may be at least amusing to those who know better; they may even have that opportunity, dearly beloved by all, of laughing at, if not with, the writer.

Many things attracted the notice of a visitor from "ayont the Tweed" that even a lengthy railway journey and some exhausting waits at weird, gloomy, half-lit railway stations were not sufficient to efface. Perhaps first might be mentioned the striking difference between Scottish and English scenery. The majority of the hills seen were grass-clad to their summits instead of the heathery slopes of "Caledonia stern and wild," the fields were divided by hedges—rustic in their unprimed simplicity—or dykes sufficiently "ragged to be artistic; these were pleasing to a photographer's vision when compared with the stiff, utilitarian wire fences on the other side of the Border. The landscape was almost invariably diversified by trees which grew here, there, and everywhere in beautiful profusion, not the stiff, business-like warriors of a northern clime, but "with verdure clad" to their very roots. Well may the Sassenach make pleasing tree studies, he has every inducement. The trees situated in the centre of fields form many pleasing backgrounds for cattle studies, and the pigs feeding in the orchards formed a scene at once quaint and unusual to northern eyes. In a word, English scenery may be described as "pretty," while the proper word for Scottish

scenery would be "grand." In both cases, of course, I speak in general terms.

The wealth and beauty of colour and arrangement in these rare old typical "half-timber" houses, of which we saw so many in the excursions last week, can perhaps best be appreciated by those who view them as novelties, while the magnificence and grandeur of the glorious ecclesiastical buildings that we were privileged to view will be for long a treasured memory. Time was all too short to allow even to be partially satisfied; the desire was ever present to "live" amongst them, at least for a long time.

It is, perhaps, too late in the day to write of the invariable kindness of Conventioners to strangers. The masters of our art were always willing and anxious to give to novices the benefit of their knowledge, and here a humble scribe would tender to many—the list of creditors is too long to individualise—his humble and heartfelt thanks.

The energy displayed by some—and perhaps in this respect some of the ladies showed a greater vitality and ability for work than the men folk—and the caution by others, were noticeable, and at times amusing. For instance, when an energetic one found a coveted view in the possession of a cautious one, the evident impatience displayed by Energy was in striking contrast to the nonchalance of Caution.

In connexion with the ancient domestic architecture, I had almost omitted mention of a feature that struck me, namely, the old builders, whether with an eye to effect or not, I am unable to say—placed the chimneys "all over the shop;" the present utilitarian age invariably, unless where they copy from the architecture of the past, always places them on top of the gable, and therefore loses a valuable means of giving variety and beauty to their work.

The field labourer is different, too, from his Scottish brother; he seems to take matters more leisurely. A Scotsman goes to work in the field coatless; the Englishmen, while he, like his Northern brother, does not wear his coat, carries it with him, probably as a precaution against any rainfall, or, perhaps, to show that he possesses such an article of attire; the latter, involving a certain degree of pride, may be the proper reason, as on one of the excursions I noticed a railway porter prominently flourishing a gold—no, I won't say it was brass—ring.

Speaking of porters draws attention to the politeness displayed by the railway companies in their announcements. They say, "You are requested to cross the rails by the bridge only." In Scotland the, railway autocrats announce, "Passengers must cross the rails by the bridge only." No request there, a peremptory demand to their humble servants, the travelling public.

Then, again, it seemed strange to see a railway station called "street," such as Oakle street; probably this may be a survival of the famous Roman Watling-street.

I have not yet tried the President-elect's three- (spot) card trick, but, even at the extent of risking the symmetry of my eyes, I intend doing so at an early opportunity. I was glad to hear Mr. Lund's lecture and see his slides, as it directed attention to a branch of photographic work that I had the honour to direct attention to two or three years ago, although in a much more humble direction. The work suggested gives great scope to the worker, and still further endears him to the favourite author whose wanderings he follows and whose life and work he attempts, however feebly, to illustrate.

The increased pleasure of a trip by boat, contrasted with the dirt, hurry, and noise of a trip by rail, renders it imperative that the Council, in arranging its trips in future years, should always include at least one trip by water.

In conclusion, let me express the thorough enjoyment the Convention was, and express the hope that I may meet the "camera-men" and ladies frequently in years to come.

### THE MEASUREMENT OF SHUTTER SPEED.

LIEUTENANT R. R. RAYMOND, of Boston, Mass., contributes the following paper on this subject to the *Scientific American* :—

There are to-day published a number of tables giving the proper time of exposure for different subjects in different classes of light, at all hours of daylight, and all seasons of the year. These tables are a valuable guide to photographers; but, in order to use them intelligently, it is necessary to know the speed of one's shutter. The figures found on the indicator dials of most shutters are far from accurate, but are generally accepted as correct because at first sight the measurement of a shutter's speed, when set for instantaneous work, appears too difficult to be attempted. It may, however, be accomplished quite accurately in the following simple manner: Take a piece of white cardboard shaped as shown in fig. 1, and draw upon it the figure shown, being careful that the upper edge of the lower black triangle is in prolongation of the lower edge of the upper triangle. Now insert the narrow part of the card in a piece of lead pipe about two inches long and one inch in diameter, and then flatten the pipe so as to fasten it securely to the card. With the addition of an ordinary two-foot rule, this is all the apparatus needed.

Select a brightly lighted wall, and mark a point about six feet above the floor or ground. Then fasten the rule vertically against the wall with its upper end exactly three feet below the mark. Set up the camera

squarely in front of the rule and at such a distance as will give the largest possible image of the entire length of the rule. Focus sharply and use a small stop.

The card should now be held so that its centre mark is just beside the six-foot mark on the wall. Fig. 2 shows all in readiness for the drop, the dotted rectangle representing the field of view of the camera.

Now release the weighted card so that it will fall close beside the rule,

and expose the plate while the card is passing the rule. This will require care, and it would be well to practise it several times without withdrawing the plate-holder slide.

The plate must now be developed, and will show a picture like fig. 3, in which the centre mark of the card is blurred by its motion. This motion must be measured by the scale shown in the photograph of the rule (never with the rule itself), and must be expressed in feet. Call this distance  $d$ .

Let  $t$  be the time in seconds that the shutter was open. Then  $\frac{d}{t} = v$ , the velocity of the card in feet per second at the time of exposure. Observe the distance that the centre of the blurred mark has fallen below the upper end of the rule. Add three feet, and the sum is the sum total distance that the card has fallen. Call this  $h$ .

Neglecting air resistance, we have from the law of falling bodies  $v = \sqrt{2gh}$ . Equating the two values of  $v$ , we have  $\frac{d}{t} = \sqrt{2gh}$ . Solving for

$t$ , we find  $t = \frac{d}{\sqrt{2gh}}$ , in the second member of which all the quantities are known.

Example.— $d = 3'' = 0.25'$ ;  $h = 4'$ ;  $g$  may be assumed as 32.2. Then

$$t = \frac{d}{\sqrt{2gh}} = \frac{0.25}{\sqrt{257.6}} = 0.0156 \text{ second, approximately.}$$

The card may be dropped from a greater height than three feet above the rule, and the greater the fall of the card the greater will be the accuracy of the result; but the greater will be the difficulty of getting the picture of the card at the proper place.

The following table gives shutter speeds from  $\frac{1}{100}$  second to about  $\frac{1}{1000}$  second with sufficient accuracy for ordinary purposes. By placing the camera at a greater distance from the wall and using a longer drop of the card, the table may be extended as desired.

Total fall in Inches	Fall of Card During Exposure, in Inches.

### DETERMINATION OF SOLUBILITY.

For a correct determination of solubility, it is important, points out our contemporary, *The Pharmaceutical Journal*, in the first place, that the substance to be dissolved and the solvent should both be quite pure. The solubility of nearly, though not quite, all substances varies according to the temperature, and this must accordingly be maintained constant and be accurately noted. For this end, the vessel containing the substances under experiment is immersed in a bath of water or other liquid, which

is kept at a steady temperature; if this temperature is above that of the surrounding air, an automatic regulation of the heat supply is best; such an arrangement is called a thermostat. Several kinds of thermostat are in use; they are obtainable from makers of scientific apparatus, and need not be described in detail here; the principle on which the heat is regulated is the same in all of them. The gas supplied to the burner by which heating is effected has to pass through a tube which is in connexion with a reservoir containing some very expansible substance, immersed in the bath itself. The connexions are so arranged that expansion of the substance in this reservoir partly closes the tube through which the gas is passing, and so diminishes the supply, while contraction again increases it.

The substance whose solubility is to be found is reduced to powder and added to the solvent until a good deal remains undissolved; the mixture is now put into the constant temperature bath and kept in a state of continuous or intermittent agitation for a long time. When no more appears to be dissolved, the excess of the solid is allowed to subside, or, if necessary, it is removed by filtration. A portion of the solution is then removed, weighed, and carefully evaporated to dryness, and the residue again weighed; in this way the exact strength of the solution is found. To check this result, the remainder of the solution and the excess of the solid are again agitated together for some time at the same temperature as before, and the strength of the solution again found, as before. Or the temperature may be raised and solution effected at the higher temperature, and then the whole allowed to gradually cool down to the required temperature and kept at this for some time, the strength being then found as previously. The results found in these ways ought to agree very closely.

#### KODAK VERSUS GAMAGE: MR. JUSTICE STIRLING'S JUDGMENT.

MESSES. KODAK, LIMITED, send us the following notes on this case, which were unavoidably held over from our last issue:—

The decision in this motion is very important to manufacturers and dealers as clearly showing the legal relation of the manufacturer and the retailer in respect of retail prices. It is evident from the judgment that every manufacturer can legally protect himself from his fixed retail prices being cut by one dealer, who seeks thereby to get an unfair advantage over other dealers. The discounts given by manufacturers are intended to give a fair and living profit to the dealer, and to him alone. If the discounts be greater than are needed for a living profit, then the assumption is that they ought to be reduced. If under-selling sets in, there is no end to the competition, and the result is that the businesses of the smaller men get extinguished. There is no question of monopoly or boycott. The dealer gets a liberal discount for himself on condition of selling at certain prices fixed for all alike, and it is a breach of faith if he departs from these conditions. He is then in the undignified and dishonest position of having to conspire with pseudo-dealers and other intermediaries to get the goods by back-stair methods, giving discounts away in order to keep up a reputation with the public of selling well-known articles at a lower price than other dealers. The great stores have given up this position in regard to photographic manufactures, and it is very unlikely that any one dealer will be able to sustain such an attitude for any length of time.

It ought to be generally known by all manufacturers and dealers that a form of invoice, with restrictions, or referring to restrictions, on a discount sheet, makes an effective contract.

Mr. Justice Stirling, in the course of his judgment, after saying that the duty lies with the vendor to take care that his stipulations are brought home in a clear way to the purchaser, observed as follows: "It appears to be the fact that circulars were published by the plaintiff Company from time to time, and all that would be necessary would be to put in the invoice of the goods a reference to the circular for the time being in force."

#### THE ROYAL INSTITUTION.

At a general monthly meeting of the members of the Royal Institution held on the 3rd inst., Sir James Crichton-Brown (Treasurer and Vice-President) in the chair, Lord Kinnaird, Mr. A. F. Lindemann, and the Hon. W. J. Ward were elected members. The special thanks of the members were returned to Mr. Henry Vaughan for his donation of 20*l.*, and to Sir Henry Thompson, Bart., for his donation of 25*l.* to the Fund for the Promotion of Experimental Research at Low Temperatures. The cordial thanks of the members were returned to the Master and Wardens of the Merchant Taylors' Company, to the Lord Mayor and Lady Mayoress, to Dr. and Mrs. Mond, to Dr. and Mrs. Dewar, to Professor William Odling, and to the Teachers of Natural Science at Oxford, for their hospitality to the members and guests of the Royal Institution during the recent Centenary celebrations. The Managers reported that they had received gratifying assurances from their guests that the Centenary celebrations, as a whole, were highly appreciated, and considered not unworthy of the past history of the Royal Institution, and of good augury for that new century of scientific work to which it has now

to apply itself. Taus Professor Cornu, on his return to Paris, reported to the French Academy of Sciences as follows:—

"La Royal Institution of Great Britain, fondée en 1799 par Benjamin Thompson, Comte de Rumford, fêta les 5, 6, et 7 juin, le Centenaire de sa fondation; S.A.R. le Prince de Galles (Vice-Patron de l'Institution), a gracieusement demandé qu'on lui présentât nos confrères et leur a remis, dans l'une des séances commémoratives, le diplôme de membre honoraire de l'Institution Royale. Lord Rayleigh et M. James Dewar ont rappelé, dans deux remarquables Commemoration Lectures, les principales découvertes faites dans les laboratoires de l'Institution Royale, par Thomas Young, Sir Humphry Davy, Michael Faraday, John Tyndall.

"Les expériences les plus intéressantes ont été exécutées; en particulier, celles qui se rapportent à l'interférence des sons et à l'hydrogène liquide ont excité un véritable enthousiasme. Nous avons pu mesurer ainsi l'immense chemin parcouru depuis un siècle, grâce aux efforts déployés dans cette belle Institution.

"Enfin l'Université d'Oxford a convié tous les savants étrangers présents à Londres à visiter ses collèges, plus de cinq fois séculaires, qui renferment des richesses d'une valeur inestimable.

"Les deux Universités de Cambridge et d'Oxford ont témoigné à nos confrères leur sentiments d'estime et confraternité scientifiques en leur conférant des titres de docteur honoraire.

"Nous rapportons donc de notre séjour parmi les savants anglais non seulement l'impression de la plus cordiale hospitalité, mais encore une véritable admiration pour la manière dont ils cultivent et honorent la science. L'histoire de ces Universités, et particulièrement celle de l'Institution Royale de la Grande-Bretagne, offre un exemple bien instructif; on voit par quelle méthode une nation, jalouse de s'élever au premier rang du progrès scientifique, d'encourager les recherches élevées et d'en faire comprendre les applications, parvient au but qu'elle s'est proposé.

"Elle choisit à chaque époque les savants les plus illustres, leur donne à la fois l'indépendance et les moyens matériels sans lesquels aujourd'hui on ne saurait réaliser de grandes découvertes.

"Il y a là un sujet de méditations et d'études pour ceux qui ont l'honneur de diriger le mouvement scientifique et qui s'efforcent de maintenir notre pays au rang élevé que ses traditions lui imposent."

It is satisfactory to be able to report that the Centenary celebrations have not affected the pecuniary resources of the Royal Institution, as all expenses in connexion therewith have been defrayed by private contributions. A balance remaining over of the sums contributed, amounting to 87*l.*, has been paid over to the Fund for the Promotion of Experimental Research.

## Our Editorial Table.

VICOL P.O.P.

Manufactured by Berger & Co., South Hill Works, Hampstead, N.W.

We have received a sample packet of this printing-out paper, which, as we mentioned a fortnight ago, is used for the purpose of producing results in colours. The specimen print submitted to us is of a pleasing character, and shows that the process has great possibilities. The working instructions are as follows:—

*Printing* should be done in the shade, and carried out rather deeper than the finished print is required to be.

*First Washing*.—Before toning, wash the prints for ten minutes in gently running water, or in several changes.

*Alum Salt Bath*.—To harden the surface of prints, soak them, after the first washing, in

Alum .....	1 ounce,
Common salt .....	1 "
Water .....	20 ounces,

for five minutes, keeping them always in motion; then wash again for ten minutes, before toning.

*Toning*.—"Viccol" P.O.P., either matt or glossy surface, works very well in any ordinary toning bath. The following formula gives splendid results, and, if made up separately in well-stoppered bottles, the solutions will keep good for a long time:—

No. 1.	
Ammonium sulphocyanide .....	150 grains.
Water .....	15 ounces.
No. 2.	
Gold chloride .....	15 grains.
Distilled or boiled water .....	15 ounces.

For use, add 2 ounces of No. 1 to 16 ounces of water, and then add 2 ounces of No. 2. These quantities are sufficient to tone a 1*s.* packet of "Viccol" to a rich purple-black. The whole of the prints should be put into the bath at the same time, as nearly as possible, and kept in constant motion. Toning is complete in six to seven minutes.

*Fixing*.—After toning, wash the prints for five minutes, and then immerse for ten minutes in this fixing bath, which should always be freshly made: Hypo, 3 ounces, in 20 ounces water. After this, the prints must

be thoroughly washed for about one and a half hours either in gently running water or many changes.

The paper, whether matt or glossy, has a rose-tinted surface before toning and fixing, when it changes to a delicate mauve, the prints resembling ordinary photographs of fine quality. If desired, pure whites may be obtained by soaking the prints in a bath composed of 20 minims of A solution (see below) in 20 ounces of water.

The colours are produced as follows:—

After fixing and washing, press the prints between clean blotting-paper to remove superfluous moisture, and apply the following solutions with a camel's-hair brush to the parts it is desired to change:—

- |    |   |
|----|---|
| A. | For flesh tints, a 5 per cent. solution of citric acid. |
| B. | " reds " " " " boric "                                  |
| C. | " pink-yellow " " " " pyro. "                           |
| D. | " blue " " " " sodium hydrate.                          |

Solution A or C gives a realistic brown appearance to such subjects in the prints as tree-trunks, masonry, horses, &c. Solution D imparts a greenish effect to foliage, &c. After colouring, slightly rinse the prints under the tap in gently running water. Finish and mount in the usual way.

#### THE "CAMERA OBSCURA:" AN INTERNATIONAL PHOTOGRAPHIC REVIEW IN FOUR LANGUAGES

Published by Williams & Norgate, Henrietta-street, London, W.C.

We have received the first number of this publication. There are French, German, Dutch, and English sections, the latter being edited by Mr. Chapman Jones, who has secured the co-operation of Colonel Waterhouse, Mr. Hector Maclean, and other gentlemen as contributors to the number. The printing, illustrations, and get-up of the new magazine are very good; but we fancy it is hardly likely to appeal largely to English readers. Nevertheless, we wish it every success.

## News and Notes.

We are informed that Messrs. J. H. Dallmeyer (Limited) have just paid an interim dividend of twelve per cent. for the past six months.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, July 26, at eight o'clock. Discussion, "The Extent to which Hand Work is permissible in Photography."

**THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.**—The prize camera for the current month has been awarded to Mr. W. E. Hickling, 19, St. Stephen's-road, Leicester, for his negative, *Picking up the Pilot off Flushing*.

Mr. W. H. ASSENDEN, 3, Vestris-road, Forest-hill, S.E., writes: "I beg to request you to insert in your next issue the fact that I have withdrawn my name from the signatories of the Nottingham Incandescent Lime-cylinder Syndicate (Limited), of Egerton-street, Nottingham, and 385, Old Kent-road, London, and at the same time have ceased my connexion as traveller and agent of the said business."

**THE KODAK EXHIBIT AT THE CONVENTION.**—Among the exhibits of Messrs. Kodak, Limited, at the Convention, we noticed some very fine enlargements on Royal bromide paper, from 4x5 cartridge Kodak negatives, the subjects being as follows:—*Sunbury Lock*, by Mr. George Davison; *Wadby, Lifemint Scene*, and *Paul Lunge with his Kodak*, by Mr. F. M. Sutcliffe; *Horses*, by Colonel Gale; *Cattle*, by Dr. Grindrod; also a series of Gloucester Cathedral, and a fine set of direct prints on Solio and Dekko papers from 12x10 negatives by Messrs. W. & D. Downey. The entire exhibit attracted the close attention of the visitors.

**THE SANDELL "PERFECT" COMPETITIONS.**—The following are the results of the June competitions:—10l. prize, *A Message from over the Sea*, Mr. W. McLean, Belfast; 5l. prize, *The Forge*, Miss Mary C. Fair, Southampton; 1l. prizes, *Bubbles*, Mr. Albert Durr, Wotton-under-Edge; *Study of Girl in Sunlight*, Dr. Llewellyn Morgan, Liverpool; *Home Lessons*, Mr. T. Knox, Belfast; *Giddy A.P.*, Mr. F. W. Fielder, Foxenden, Dene-road, Guildford; three interiors, Mr. Harold Baker, Birmingham; *Gladiolas*, Mr. H. C. Leat, Bristol; two snap-shots, *Morning off Deptford*, *Evening off Greenwich*, Mr. T. K. Beaufort, Westminster; two snap-shots, *Evening on the Mersey*, Mr. E. A. Spivey, Colne, Lancashire; three interiors, *West Monmouthshire School*, Mr. H. Dunning, Usk; interior, *Falkland Palace*, Mr. J. Terras, Markinch, N.B.

**MESSRS. B. J. EDWARDS & CO.'S EMPLOYEES' OUTING.**—On Saturday last the *employees* of Messrs. B. J. Edwards & Co., The Grove, Hackney, took their annual outing. The place selected this year was Yarmouth, to which the party were conveyed by the Great Eastern Railway. Upon arrival, the company disported themselves as they thought fit; some took sea trips, others sea dips, whilst, again, others preferred the country, and went for a drive until they all met at a given time at the Bath Hotel, where a capital dinner awaited them, to which they all did ample justice. The head of the firm (Mr. B. J. Edwards) presided, and Mr. Thomas Cowderoy filled the vice-chair. After the cloth was removed, the usual loyal toasts were given by the Chairman, and then the toast of "Success to the Firm" was given in a neat little speech by the Vice-chairman, and suitably responded to by Mr. Edwards. Occasion was then taken to present to Mr. J. L. Newman a pair of solid gold sleeve links in recognition of his valuable services as Hon. Secretary to the outing fund, and his untiring exertions in bringing these outings to such successful terminations year by year. The company met again later for tea, and then made for home after a most enjoyable and pleasant day.

## Patent News.

THE following applications for Patents were made between July 3 and July 8, 1899:—

**TREATING PLATES AND FILMS.**—No. 13,832. "Improvements in Apparatus for Treating Photographic Plates and Films." W. P. WETHERED.

**ANIMATED PHOTOGRAPHY.**—No. 13,903. "An Improved Method of and Apparatus for Conducting certain Photographic Operations, principally applicable in connexion with Animated Photography." C. RALEIGH.

**WASHING PLATES.**—No. 13,987. "Improvements in or relating to Apparatus for use in Washing, Drying, or otherwise Treating Photographic Plates." Complete specification. G. GEIGER.

**THREE-COLOUR CAMERA.**—No. 14,021. "Camera for Three-colour Work." W. C. MASSER.

**SHUTTERS.**—No. 14,075. "Improvements in Photographic Shutters." THE THORNTON-PICKARD MANUFACTURING COMPANY (Limited) and C. G. WOODHEAD.

**EXPOSURE METERS.**—No. 14,070. "Improvements in Photographic Exposure Meters." A. WRIGHT.

**FILMS.**—No. 14,094. "Improvements in Photographic Films and in Apparatus for using same and connected therewith." J. E. THORNTON.

**CAMERAS AND TRIPODS.**—No. 14,102. "Improvements in or in connexion with Cameras and Camera Tripods." F. W. BRANSON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
25.....	Ashton-under-Lyne.....	Excursion: Mow Cop for Morton Hall. Leader, Walter Leigh.
25.....	Birmingham Photo. Society ..	Social Evening.
25.....	Hackney.....	Exhibition of June Excursion Prints
26.....	Kingston-on-Thames.....	Excursion: Zoological Gardens. Leader, J. F. East.
26.....	Photographic Club.....	Discussion: The Extent to which Hand Work is Permissible in Photography.
26.....	West Surrey.....	Open Night
29.....	Birmingham Photo. Society ..	Excursion: Rugby and Dunchurch. Leader, R. Haines.
29.....	Borough Polytechnic.....	Excursion: Richmond Park. Leader, S. H. Kemble.
29.....	Hackney.....	Excursion: Zoological Gardens. Leader, W. L. Barker.
29.....	Oldham.....	Excursion: Vale Royal. Leader, James Brooks.
29.....	South London.....	Excursion: Eynsford. Leader, C. Churchill.
29.....	West London.....	Excursion: West Drayton.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 13.—Mr. F. W. Mundy in the chair.

Mr. A. L. Henderson sent up a couple of positives, showing what might be done in the direction of the utilisation of bad or light-struck plates. The first positive was on a light-struck bromide plate which had been printed out after treatment with a solution which, for experimental purposes, was composed as follows:—

Silver nitrate .....	10 grains,
Citric acid .....	5 "
Water .....	2 ounces,

with sufficient ammonia to redissolve the precipitate formed. The plate is dried in the dark, with no washing. After printing, the plate is washed in salt water, fixed, and toned in a gold and sulphocyanide bath.

Mr. A. HADDON thought that an ordinary bromide plate of any speed would be too coarse in grain to look well treated as had been described. A slow plate would do, but, of course, the point was the utilisation of old plates.

Mr. MACKIE said that bromide of silver would print out in the presence of free silver similarly to the other forms of silver.

Mr. J. A. SINCLAIR showed a negative on Sacco film, which presented no difficulties of manipulation and was easy to handle. He found it stripped off its support with ease, and took to its supplementary supporting piece of gelatinised paper without any trouble.

Mr. J. E. HODD thought the negative was rather granular in appearance. If the emulsion could be coated in the first place upon celluloid, from which it should just as freely strip, this drawback would be overcome.

### PHOTOGRAPHIC CLUB.

JULY 12.—Mr. W. R. Stretton in the chair.

A vote of sympathy with Mr. Child Bayley in his unfortunate accident at Gloucester was passed, on the proposition of Mr. FOXLEE, and the Secretary was authorised to write and give expression of the same in the name of the Club.

Mr. PERCIE T. EDWARDS sought some information on the question of photo-transfers for application to porcelain and for burning in on pottery. The original he had was an ordinary silver print, but he was not clear whether the transfers were to be simply for transfer, or whether they were to be such as could be burnt in upon pottery, &c.

Mr. FOXLEE said that the image must of necessity be in a vitreous pigment if the transfers were needed for burning in. Then, again, it was necessary to know the method of firing in to be followed. Some potteries fire in at a mild heat, and others at a great temperature.

The names of Messrs. Morgan & Kidd (of Richmond), Pendry (of Nottingham), Grundy (of Derby), &c., were mentioned as carrying on ceramic work.

Mr. FOXLEE, continuing, said that the transfers could be made by the carbon process, using a pigment of a vitreous character; or, as by Grundy's method, the collotype process could be used, and an image, in vitreous pigment, built up of several printings to give sufficient body to the result, be burnt in upon the desired article. Mr. Foxlee said that observers on railway stations, &c., would also have seen a method of burning in upon enamelled iron, by which some really good work had been done. Attempts at imitation of enamels had been made, and it would perhaps be remembered that at the last Crystal Palace Exhibition he showed a collodion transparency on clear glass which had been backed up and cemented upon a piece of opal, the margins being afterwards bevelled off. This made a very effective picture indeed.

Mr. HANS MÜLLER produced a print which he had seen made at the Royal Photographic Society's *Soirée* at 66, Russell-square, by the inkless electric printing machine. The paper, it may be said, is chemically prepared, and is placed in contact with the usual printing surface, when an electric current is passed through. The result is that the chemical is decomposed, and the type or block is imprinted upon the paper. The print in question had been in his pocket since its production, and, strange to relate, had gone to a deep muddy colour. No explanation was forthcoming, but the behaviour of the paper was considered peculiar. Another instance was mentioned in which a print had partly been exposed, and where so exposed had gone decidedly yellow, while the unexposed parts were unchanged.

### FORTHCOMING EXHIBITIONS.

1899.

- |                       |   |
|-----------------------|---|
| August .....          | One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C. |
| Sept. 22-Nov. 4 ..... | Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.  |
| " 25-Nov. 11.....     | Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.   |
| October 18-24 .....   | Croydon Camera Club.  |
| " 22-Nov. 19...       | Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.   |
| Nov. 27-Dec. 18 ..... | American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.     |
| December 7-9 .....    | Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.   |

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

### Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### KROMAZ COLOUR PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—We notice in a report of the Convention you mention, in connexion with our exhibit, that "Messrs. Watson & Sons showed Ives's kromaskop, which attracted the delighted attention of visitors." This is not correct. The colour process which we exhibited and explained was the "Kromaz colour photography," invented and patented by Barnard & Gowenlock, and for which we are sole agents.

As your description is likely to mislead many who examined and spoke very highly of the process, we shall be obliged by your kindly correcting the notice in your next week's issue.—We are, yours, &c.,  
W. WATSON & SONS.

313, High Holborn, London, W.C., July 17, 1899.

### CALCIUM CARBIDE.

To the EDITORS.

GENTLEMEN,—In answer to your correspondent, Mr. J. V. Robinson, I would suggest he sends his samples of calcic carbide and deposit, after generating acetylene gas, to some other specialist, if he wishes his own

opinion confirmed, or otherwise. Personally I can do nothing more, for I should hesitate to again approach Professor Vivian B. Lewes on the subject after his courtesy in once giving an opinion. Experts like him are busy men, whose time is of considerable value and who seldom give an opinion without receiving a substantial fee.—I am, yours, &c.

London, July 16, 1899.

GEORGE R. BAKER.

### BRAIN WAVES AND PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Will you kindly give an opportunity to the many artistic and other workers you, doubtless, have amongst your readers to express their views on the action of the brain waves excited in the operator by the object to be photographed in their action on the "conjugate foci;" for, as the optical relation between conjugate foci involves the reversal of the direction of the light, so may it be that the brain waves I am about to describe are themselves involved in the reversal of the direction of the light, thereby establishing a definite individual relation between the operator and the object. Then, of course, it will be obvious that, as the brain waves thus take an actual part in the production of the picture, so will each definite individual feeling in the brain be expressed in the picture. It should, therefore, follow that an indispensable condition of a good photograph is that the operators should form, as nearly as possible, a perfect conception of the object, and then bear that conception in mind as intensively as possible. The production of the brain waves for the purposes of thus affecting a photographic plate may be described as incident in the larynx, continuously as nearly as may be, and analogous to the heating, luminous, and chemical action the discharge of each impulse liberates, by means of which each impulse gives to the vibrations in the larynx its individual pitch, which is emergent from the sympathetic movements of the oral cavity of the mouth, tongue, and lips, whose slight, silent movements conjugate, continuously as nearly as may be; the vowels and consonants forming the silent symbols in which the brain thinks of each impulse, into undulations of invisible light, whose vibrations, with the velocity of light, and the wave-length given by each impulse, form conjugate foci to the rays from the object to be photographed, for the reason that the light which the oral cavity of the mouth, tongue, and lips conjugate correspond in their vibrations to the picture which the object has formed on the brain of the operator; that is, the frequency of the emergent vibrations (wave-length) from the oral cavity of the mouth, tongue, and lips correspond to the frequency of the vibrations (wave-length) from the object, as seen by the brain of the operator. That the oral cavity of the mouth, tongue, and lips do conjugate the vowels and consonants which form the symbols or silent speech in which the brain thinks, may be experienced by any person who will quietly observe himself. For example, I feel myself conjugate each letter and each word I am now engaged in writing. But this silent faculty of speech is co-extensive with each and all mental and bodily movement whatever. So that, such being the case, then the emergent sympathetic waves (all things being equal) are indispensable to the production of a good picture, and may be said to form both the physiological and psychological bases of the quality of the picture.

Trusting that you may consider the above of interest to your numerous readers,—I am, yours, &c.,  
WM. CLIHAN.

2, Brunswick terrace, Victoria-road, Bowden, Cheshire.

[Agreeably to our correspondent's request, we insert his letter, but we must not be understood as supporting his somewhat curious theories.—EDS.]

### Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

- L. Varney, Bridge-street, Buckingham.—Photograph of 1st Bucks Rifle Volunteers.
- C. Mayne Clark, 2, Station-parade, Exmouth.—Two photographs of kitten with two faces.
- W. M. Sweetman, 23, Chesham-flats, Duke-street, W.—Four Photographs of Rev. Father Ignatius.
- T. Wallace, Eskbank-road, Dalkeith.—Photograph of H.R.H. the Prince of Wales and party at Dalkeith.
- B. T. Watson, 461, Anlaby-road, Hull.—Photograph of Australian cricketers. Photograph of English cricketing team.

B. MCGRATH.—We see nothing to object to in the advertisement.

BAS-RELIEF.—R. Pietzner, Vienna; The Taber Bas-relief Co., 141, New Bond-street, W.

"NOVITAS."—The address of the firm who supply the paper is Scholz, Binsfeld-road, Clapham, S.W.

**EAGER.**—If you registered your photograph, you are in a position to make a claim—not otherwise.

**INDIA.**—1. South Africa would be about your best ground. 2. Encaustic paste [see formulae in our ALMANAC].

**W. L. BERRY.**—We believe the firm to be respectable, but, if you have any doubts on the matter, why not adopt the deposit system?

**H. SHIRINGTON.**—We have no personal knowledge of the firm. Sorry we cannot help in the matter. It must be obvious to you that we cannot be responsible for the *bona fides* of every advertiser in the JOURNAL.

**WOOD'S DIFFRACTION GRATINGS.**—A. F. J. R. says: "Will you kindly inform me whether the diffraction gratings as described by Professor Wood are on sale in England, and, if so, their price?"—Not obtainable yet, so far as we know.

**DARK ROOMS IN IRELAND.**—CELTIC asks: "Could you tell me if there are any dark rooms in Drogheda, Navan, Kells, Trim, or anywhere within a few miles from these places?"—Will some Irish reader oblige with the information?

**ENLARGED NEGATIVES.**—INQUIRER asks: "Would you kindly say if you consider that an enlarged transparency and the contact-printed enlarged negative could be successfully produced by the use of negative paper?"—Yes; but, of course, the grain of the paper would be apparent in the finished result, though not offensively so.

**RECOVERING GOLD.**—R. T. W. says: "Could you oblige with the best way to get the gold out of the sulphocyanide bath?"—The most economical way of getting the gold out of the bath is to exhaust it by toning prints in it. The gold may, however, be precipitated by a solution of the protosulphate of iron, as from any other toning bath.

**STEREOSCOPIC PHOTOGRAPHY.**—M. M. LAHIRI says: "Will you kindly let me know—(1) where I can get cheap American stereoscopes, and also (2) whether Theodore Brow's stereoscopic transmitter, advertised in your JOURNAL of May 19, p. 17, can produce good stereoscopic pictures?"—In reply. 1. Of S. Guiterman & Co., 35, Aldermanbury. 2. Yes.

**STARTING IN BUSINESS.**—VQUIP says: "I have started photography professionally, and should feel greatly obliged if you could give me some good practicable ideas how to work a portrait club, and a good method of canvassing; also, is it customary to appoint agents? if so, at what commission are they usually paid?"—Some reader may be able to help.

**'SUN' DARK SLIDES.**—E. WATZLAFF says: "I should be so pleased if you could let me know where I could get double dark slides made by the 'Sun' Camera Co. Lim., Leeds? A letter addressed to that address came back with the remark 'not known at that address,' and, as my camera has been made there, I thought it might be best to get the extra slides from the same place."—In reply: Try Lonsdale Brothers, 22, Goswell-road, E.C.

**S TICKY NEGATIVE VARNISH.**—J. D. F. replies: "I have a lot of negative varnish which has become sticky; whilst printing I can hardly get the prints from it. What is the best to do with it to remedy stickiness? also to thin the varnish?"—As the composition of the varnish is not stated, we can give no advice. We should say, however, that the best thing to do would be to discard it altogether. Possibly it may be thinned with methylated alcohol.

**ANAGLYPHS.**—"SOLID" says: "In a recent number of the JOURNAL you commented on the anaglyph, and stated that it owes its origin to Du Hauron. Could you kindly favour me by informing me whether there is any publication from which I can obtain particulars by Du Hauron or others on the principle of the anaglyph?"—In reply: *La Triplique Photographique des Couleurs*, by A. Ducos du Hauron, published in French by Gauthier Villars et Fils, Quai des Grands Augustins, 55, Paris.

**PHOTOGRAPHS OF CRYSTALLISATION PROCESS.**—R. FRANCIS says: "I wish to take some instantaneous photographs of the process of crystallisation from a colourless solution poured on to a glass plate and allowed to evaporate spontaneously. They are for educational lantern slides, and I find it difficult to light them so as to get sufficient contrast. Can you advise me as to the best method? The space to be included is about two inches square."—We should recommend you to get an elementary treatise on the microscope, as the subject is too long a one to be usefully dealt with in this column.

**CRIPPLE** writes: "Thanks for your reply. The notice was not given by the owner's solicitor, but from the man I took the house of, a builder, who was then the owner. 1. Have I not a right to be instructed by the new owner or solicitor before paying any more rent? I have paid two quarters' rent since he sold the house. 2. Would it not cancel the notice, he not being a solicitor?"—1. No. As you have been paying the rent to the one who let you the premises, pay it to him now, as you have received no notice from the new owner to the contrary. 2. Not under the circumstances, particularly as you formally accepted the notice to quit.

**BICHROMATE POISONING.**—RASH says: "I have recently been doing a little carbon printing—made about a couple of dozen half-plate pictures, perhaps a few more—and since then I have had a rash on my back, which itches and smart most annoyingly. Can you tell me of a remedy, or how to avoid the ill effects of the bichromate in the future?"—We should say that the bichromate has nothing whatever to do with the rash, and its cause should be sought for elsewhere. The ill effects of the salt are confined to the parts that come in contact with the solution, and rarely, if ever, extend beyond. It is also pretty certain that no trouble would accrue from so limited a use of the carbon process.

**LENS QUERY.**—A CONSTANT READER OF THE JOURNAL asks: "What sort of a lens would you recommend me for a studio which is only twenty feet long? As I like to go in for high-class portraiture, the question is, Will I be able to produce good work in so small a place? Also, would it be advisable to have one camera for the studio and outdoor work, as I cannot afford to buy two sets? I am not quite certain about the size of studio; I may be able to have it up to twenty-seven feet perhaps. I should like to have a lens which would cover from a cabinet up to 15×12 for the studio."—In a studio of only twenty feet long lenses of short foci must be used, and unpleasant perspective put up with. Even in a studio twenty-seven feet long it will be impossible to use a lens that will cover 15×12 for full-length cabinet portraits. We should recommend two lenses, one specially constructed for cabinets, say, eleven or twelve inches focus, and the other for larger size. One camera will answer for both purposes.

**ENGRAVING SMALL ARTICLES.**—BRASS writes: "I beg to ask for a little assistance, if possible, through the columns of your estimable paper. I have a considerable number of small metal articles to engrave. To engrave them by hand will take me too long, as I have only a short time to get them done. Can you tell me how to do them by some photo process quickly, and cheaply if possible? If there is any process described in the back volumes of the JOURNAL, I shall be extremely grateful for the information."—The kind of "small articles" to be engraved is not mentioned. Photo-engraving processes are principally confined to flat surfaces, and the small articles are probably not such. If our correspondent has had no experience in the photo-engraving processes, he will probably find that engraving by hand will be the quickest and cheapest method to him, as it would, in all probability, take him very much longer to make himself proficient in photo-engraving than to do the work in the ordinary way.

**A BUSINESS MATTER.**—PHOTO-ARTIST writes: "I should be glad if you could find space in your next issue to answer the following: I have had an assistant who has had charge of a branch studio for me. He has left me, and started business for himself in the same town. He has been exposing prints in his show-case taken at my studio, and he also has had men canvassing for orders with specimens taken at my studio; they have been taken and finished by him, but I have never given him permission to use any of the prints, which are from negatives in my possession, and which he has taken away without my knowledge and permission. Could you oblige by telling me what remedy I have, as I find he is doing me considerable harm by going round to all my former customers and telling them that the photographs are all his own taking?"—If the prints were made from your negatives, in your time, and with your materials, without your permission, we should say the man can be proceeded against criminally, for it is nothing less than theft. Before proceeding, however, we should advise you to consult your solicitor.

**DEVELOPMENT AND PRINTING.**—ESPERANCE says: "1. I find that some of my negatives present a mottled appearance, due, I understand, to imperfect washing after the alum bath. Is this injurious to the negative, and will it produce fading? If so, can it be in any way removed? The mottled appearance is scarcely noticeable in the prints. 2. Is there any means of removing pyro stains from the hands, and especially from the nails? 3. Can you give me some information as to the use of matt and glossy papers in printing? I am using Solio (5×4) at present, both glossy and matt. The latter, however, seems to be unsuitable for most negatives, especially if detailed or architectural. Is the use of glossy or matt surfaces solely a question of taste?"—1. Mottling may be due to several causes. Not rocking the dish during development is a very general cause. Without seeing the negatives we could not give a decided opinion. 2. The stains can generally be removed by moistening the parts with an acid, such as citric, oxalic, dilute hydrochloric, &c. 3. Simply a matter of taste. A matt or rough surface paper is not so well suited for small negatives with fine detail as one with a more glossy surface.

**REVERSAL.**—ALBERT ENGLAND says: "Will you kindly inform me in your JOURNAL what is the cause of reversal of image, and how can it be avoided? I had some interiors to take, and used —'s plates, developed according to their own formula. They were not backed. As I wrote to them on the subject, and they said there was no use in doing so, I took a room with windows at the end, fairly lighted, and gave twenty minutes' stop, f/22, Ross-Zeiss lens. I took some more same day at the same house, and did not get reversal in these cases. The window was not open to the sky, there being trees in front of it, yet the whole window is reversed. As you will see, it was not over-exposed in the shadows; in fact, I took the same room a few days before under the same conditions, and gave about eleven minutes, but it was very much under-exposed. Would backing have stopped it? Any particulars you can, give me, and, if you can refer to any work that I can get on the subject, I shall feel obliged."—The reversal is brought about by over-exposure of the window. The remedy is to subdue the light coming through it, give less exposure, and develop tentatively, so as to get out all the detail before the negative acquires too great a density. There can be no harm in backing the plates, though the makers say there is no necessity for it.

\* \* Several answers to correspondents unavoidably held over.

#### NOTICE.

With the present number of the JOURNAL we issue a half-tone print of the group of members of the Fourteenth Annual Photographic Convention of the United Kingdom, assembled at Gloucester during the week July 10-15, 1899. The negative was taken by Mr. A. H. Pitcher, of Gloucester. A key and list of names will be published next week.

## EX CATHEDRA.

At the offices of Messrs. W. H. Ward & Co., 119, Shaftesbury-avenue, W.C., there were given this week demonstrations of a new machine for employment in colour printing, the invention of Mr. Ivan Orloff, Chief Engineer and Manager of the Russian Government Printing Works at St. Petersburg. The salient points of the new machine are thus indicated: In colour printing by the ordinary method the successive colours are applied one at a time as the preceding one becomes dry. The Orloff machine puts down all the colours at once, and as quickly as a single colour could be printed by the old means. It is claimed that not only does the Orloff machine print quicker, but the work is superior as regards "register" to anything ever produced by the usual means. For the first time in the history of colour printing, the colours are not only applied to the paper simultaneously, but with such perfect "register" that in any number of impressions no two copies will differ from each other.

\* \* \*

MOREOVER, it is pointed out that one of the difficulties in ordinary colour printing is the slight shrinkage and expansion

of the sheets of paper between the times of applying the successive colours, owing to the continual variations of temperature and moisture in the air, which affect the measurement of the sheet by several millimetres, more or less, and make perfect "register" impossible. The Orloff machine overcomes this difficulty entirely, and also makes perfect "register," no matter how thin the paper used. The Orloff machine was designed to print elaborate multi-coloured patterns to prevent the possibility of forgery by photographic agency. All other bank notes can be so perfectly copied, by this means as to defy detection. The Russian notes have elaborate interlaced designs made up of fine lines, which have the most intricate variations of colour, so perfectly printed that no two notes in a million are found to vary in the disposition of their interlaced patterns.

\* \* \*

THE prospectus adds that the perfection required for the printing of such bank notes has rendered the Orloff machine available for artistic as well as commercial colour printing. No such prospect was within the view of the Russian authorities when they encouraged the inventor (who was not a printer, but a weaver) to make the attempt to produce unforgeable notes, but the reward was held out that he would be at liberty to realise his invention by patents for other countries if he succeeded in his task. As yet the Orloff machine has been in operation only in the Imperial Printing Works at St. Petersburg, within the walls of which it was invented, and where there are now thirty-two of these machines in full work, each producing at the rate of 800 to 1000 sheets per hour of the new issue of the Russian paper money, and also bank notes for the Chinese Government.

\* \* \*

So far the prospectus. What we actually saw was this: A block for each colour is attached to a large revolving cylinder, and, when the machine is set in motion, by an elaborate system of gearing the different rollers apply to each block its own particular colour. When all the blocks, save the one which is to give the final impression, are inked, the colours from these blocks are laid down on what appears to be a gelatine roller brought into contact with them, and from that roller the deposits of colour are transferred to the actual printing block, and thence to the paper by cylindrical movement. Examina-

tion of a number of prints, containing no less than seven different colours, showed that the results were perfectly in register. The Orloff machine is a massive piece of engineering construction, and it appears to do its work exceedingly well and quickly. The results we saw were produced from hand-engraved blocks in metal, but it is anticipated that half-tone work and photogravure will be produced from the machine. The registration appears to be faultless, and, so far as we are able to judge, the machine should have a great future before it in colour printing.

\* \* \*

THE last sitting of the session of the Select Committee of the House of Lords on the Copyright (Artistic) Bill was held last week, Lord Monkswell presiding. Mr. Herbert Bentwich, solicitor, expressed his opinion that there should be a distinction between photographs and works of fine art, with the exception that photographs of works of art should have the same term of protection as the original works; photographs taken from nature should have a shorter term; photographs should not be included in works of fine art. He emphasised the hardship of the proposed registration requirements on owners of small works, such as Christmas cards and advertisement drawings, and suggested that a mark on each card, &c., giving the date of publication, the name of the owner, and the fact that copyright was claimed, should be sufficient. The Chairman announced that this would conclude the evidence for this session, and that he hoped the Committee would be re-appointed next session.

\* \* \*

Our contemporary, *Anthony's Bulletin*, contains particulars of a decision, in regard to the photographing of criminals and placing their pictures in the New York Rogues' Gallery, which has lately been rendered by Justice Truax in the Supreme Court of the United States. He was asked to grant a writ of peremptory mandamus to restrain the Police Commissioners from taking the picture of one Thomas Joyce, and placing it in the Rogues' Gallery, after the said Joyce had been convicted of an assault and sentenced to six months in the workhouse. It being shown in response that Joyce had formerly been arrested, and that he was an associate of criminals, the application was denied, Justice Truax holding that these facts were sufficient to warrant the action of the Commissioners. In giving his decision, Justice Truax quoted Professor Tiedeman's treatise on the limitations of police power, as follows: "Another phase of police supervision is that of photographing alleged criminals and sending copies of the photographs to all detective bureaux. If this be directed by the law as punishment for a crime of which the criminal stands convicted, or if the man is, in fact, a criminal, there can be no constitutional or legal objection to the act, for no right has been violated."

\* \* \*

JUSTICE TRUAX proceeds to say that, under the Consolidation Act of the city, the duties of the police were, among other things, to preserve the public peace, prevent crime, detect and arrest offenders, and protect the rights of person and property, holding that one of the ways to carry out this end is to know who are the habitual criminals, and that the easiest way for the recognition of such is by their photographs, and, in view of the preceding, he held that, if any wrong had been done the relator, it was in the nature of a libel, for which an adequate

remedy at law is provided. We have not heard of a case analogous to this in Great Britain. Mr. William Sikes, we take it, is not troubled by such qualms of delicacy as his American congener, and we doubt, if he took it into his head to object to his photograph being included in the archives of Scotland-yard, whether there would be a probability of an English Judge seriously considering such an objection. The English law has a tendency to over-nicety in its treatment of criminals, but the line has to be drawn somewhere, and we think it should be drawn at excessive-scrupulosity in the matter of exhibiting the portraits of convicted criminals.

\* \* \*

We have frequently published extracts from the advertisement columns of our Antipodean contemporaries indicating the *bizarre* business methods of Australasian photographers, and illustrating the absurd lengths to which price-cutting is carried. A friend now favours us with copies of two advertisements which lately appeared in the *Sydney Morning Herald*, which show that there is still a lower deep than those we have previously explored. The first runs: "Eden: the leading photographer. The volume of business done at the Eden Photo Studios has been increasing by leaps and bounds beyond all anticipations, and, large as the new premises are, they have proved too small for the coping with such a rush of orders as were lately given at the studios, and for the first time in our Sydney history we had to disappoint our customers by keeping them waiting for their portraits; but this trouble is all over now, and we have made more extensive arrangements for the future. There are two reasons for the greatness of our custom—the first is that we spare no expense on our establishment and the production of first-class work; and, secondly, that in fixing our prices we do not consider how much profit we can get, but how little we can do with, and as a consequence our prices are (as most people who write their testimonials of our work state) a marvel of cheapness. Years ago photography was considered so high a profession that a photographer would almost want a guinea profit to look and say which side of your face was best to be photographed. Now, since the introduction of dry plates, bromide papers, &c., the work has become so simple (*sic*) that it seems the last resort of the commercial failure to *become a photographer*. Mr. Eden has given consideration to the fact that, as photography has become a trade, it is only deserving of trade profits, and thus the prices at the Eden Photo Studios are considerably lower than any other respectable house in Sydney."

\* \* \*

THIS advertisement admits of a variety of interpretations. One of them, the most obvious, can scarcely advantage either Mr. Eden or his profession, for it is a hint to all the weeds and wastrels of commercial life to take up professional photography in the expectation of doing what Mr. Eden boasts of doing, *viz.*, a business which advances by leaps and bounds. But there is something more. Mr. Eden's photographic business is advancing by such great leaps and bounds that he has made an addition to it in the shape of a tailoring department. He says: "If you want to dress well and at a small cost, then you should go to the Eden Tailoring Company, at the Eden Photo Studios' new building. You can make your choice from the very best of materials, and, after our first-class cutters have measured you, the suit is hand-made in the very best style. Bear in mind this is not a

factory-made suit, but made by men who are paid the low prices for hand work. Mr. Eden pledges his reputation on these suits being as good as what one usually pays from four to five guineas for, and yet the Eden Tailoring Company only charge 57s. 6d. for the whole suit. It will pay city gents to visit us." Only a few weeks ago we quoted from a Sydney contemporary a lamentation that it seemed difficult, if not impossible, to raise the status of Australasian professional photography. Can it be wondered at?

\* \* \*

THE use and abuse of lenses in taking large direct portraits is touched upon in our leading article this week.—Mr. Alfred Watkins describes an interesting application of his well-known method of development by time, or without light, to the manipulation of colour-sensitive plates.—The Kromaz, the newest system of colour photography by means of stereoscopic transparencies, now being introduced by Messrs. Watson & Sons, of 313, Holborn, London, is described.—We also print full instructions for the development and manipulation of Messrs. Wellington & Ward's new "dry" stripping film.—"Adurol" forms the subject of a brief report by Dr. J. M. Eder, who, in comparing it with hydroquinone, gives the advantages to the newer reagent.—Some little interest may attach to the method of printing from unfixed negatives described by Herr Goldschmidt; but the idea is not a new one, and in our opinion is not patentable.—With this number of the JOURNAL we also issue a numbered key to the Convention group given last week. Will those gentlemen who helped us with some of the names kindly accept our thanks for their co-operation?

### LARGE DIRECT PORTRAITURE.

At one of the recent meetings of the Photographic Club, when reference was made to some large direct portraits on plates 20 × 16, by Mr. Witcomb, of Buenos Ayres, a remark was made that there was a greater difficulty in getting orders for large direct work than there was in executing it. Mr. Snowden Ward, in reply, said that in the United States large direct photographs were much favoured. We know also that there is a considerable business done in them on the Continent—France, Germany, and elsewhere. Seeing that large direct portraiture is so much in favour, alike in the States, on the Continent, and in the Argentine, and we are told by opticians, and also by dealers in second-hand apparatus, that the majority of the large lenses for portraiture they sell are for export, and not for home use, it will be well to inquire why this is the case.

It must be admitted that a good large direct picture—up to a certain size—has a delicacy and charm about it that is not possessed by an enlargement. Perhaps one reason why there is so little demand for this class of portrait here is that English photographers do not make such a feature of them as do their confrères abroad. Another reason, and probably a greater one, is that, when a feature has been made of them here, they have not been so pleasing in character as are those of the smaller sizes, owing to the violence of the perspective, caused by the camera being brought too close to the sitter through the use of lenses of too short foci, a thing studiously avoided in the States and on the Continent. This subject has frequently been dealt with in our back volumes.

Many photographers here make the mistake of using lenses on the full-size plates they will cover; although they do this with the larger sizes, they do not do so with the smaller ones, or, at least, to the same extent. For example, the most general lens for cabinets, the size of which is  $5\frac{1}{2} \times 4$  inches, is one of from 11 to 12 inches equivalent focus, and when used for this size the perspective is pleasing, and this very largely conduces to the popularity of the cabinet picture; but, as most are aware, a good lens of that focus will cover a much larger plate when moderately stopped down.

The late Mr. J. H. Dallmeyer laid it down as a rule, some thirty years ago, that the equivalent focus of a lens should be at least double the longest dimensions of the plate upon which it is used, and that has never been controverted. The famous portraits by M. Adam Salomon, which created such a *furor* in the "sixties," were about 10 × 8 inches, for example, and were all taken with a lens of 20-inches focus. Now, what applies in the case of small pictures applies also, and in a greater degree, to large ones.

Keeping these facts in mind, we will now see how opticians catalogue their large lenses. We have now before us the catalogues of our two leading opticians, Ross and Dallmeyer. In each of these are quoted lenses, suitable for portraiture, in three series: the portrait combination; the "D" group or universal; and the rapid rectilinear or symmetrical of almost, in each list, identical foci, and to cover similar size plates. We will quote from the latter's catalogue, because in it the equivalent focus of the portrait lens is given, while in the other the back focus only is mentioned. We find there a portrait lens of 30 inches focus, a "D," or group lens, of  $30\frac{1}{2}$  inches, and a rapid rectilinear of 30 inches focus, so that, practically, the three lenses are of identical foci. The first-named is catalogued to cover 20 × 16, the second 18 × 16 to 22 × 20, and the third similar sizes, and the reputations of the two makers are sufficient to guarantee that they will cover the sizes stated; but should photographers use them for the full-size plates?

Bearing in mind what has been said with regard to the smaller sizes, say the cabinet, neither of these lenses should be employed for plates larger than 15 × 12 if we wish to obtain pleasing results, so far as perspective is concerned, and it may be mentioned that as to the size, we find upon inquiry, they are used for abroad, where large direct portraits find favour with the public. When used for sizes of half the focal length of the lens, the camera is placed at a considerable distance from the sitter, and a pleasing perspective is obtained. When, however, the lens is used for the larger size it is capable of covering, the camera has to be approached very close indeed to the subject, perhaps to within 6 or 8 feet, with the result of violent and unpleasant, though still true, perspective, the foremost portions of the features and figure appearing to be distorted.

Our older readers will remember that, some five-and-twenty years ago, the late Mr. Crawshaw, with the laudable intention of encouraging large direct portraiture—though he was ill advised in the matter—offered some very handsome prizes: fifty pounds for the best life-size portrait taken direct, and twenty-five pounds for the second best, and other prizes for smaller sizes. They will also remember, when the portraits were shown, the comments that were made upon them by the press generally, and the terms used with regard to them being such as, "monstrosities," "caricatures," "hideous," &c. This was not to be wondered at, when it is considered that to pro-

duce a life-size portrait the lens must be at the same distance from the sitter that it is from the focussing screen of the camera. Now, we believe that the lenses mostly used for these portraits were about 36 inches focus, hence it will be seen that the camera had to be brought to within 6 feet of the sitter, therefore there was little to surprise at the terms applied to the result.

The object here has been to point out that the reason why direct portraiture finds so little favour here is that many who have essayed it have made the mistake of using lenses on plates the full size that opticians make them to cover. In doing that, the camera has to be placed very close to the sitter, thus getting very unpleasant results; whereas, if it were placed, say, 15 or 20 feet away, the same pleasing picture, as cabinets are, would be obtained.

We intended to have said something on the most suitable lenses for large direct portraiture, but that must be deferred till a future occasion.

**Foci of Lenses Altered by Heat.**—One of the factors affecting the performances of lenses that have received little recognition is the action of heat in altering their foci. Professor Barnard has made a number of measurements bearing upon the subject, so as to ascertain if any possible change would necessitate corrections in specially delicate investigations. During the last year observations of the focus have been made at temperatures varying between 22° below and 80° above zero (a range of 102°). The means of the various observations made, extending over nineteen nights, showed a decided difference in the focus, it being found that the object-glass shortened .26 more than the steel tube which carried it. Micrometric measurements were made of the differences of declination between certain stars showing a difference of nearly .2" when observed in July to September and January and February. The net result is the decision announced by Professor Barnard that in exact work the differences so produced by temperature ought to be taken into account.

As regards the altering of the figure of an optical arrangement, it may be noted that, with the huge telescope which is in course of construction for the Paris Exposition, the mirror, about six feet wide, is so affected by the merest heat of the hand placed on it for a few seconds, that, when the image of a round luminous point reflected from it is examined by a telescope, a distinct deformation of the image is produced.

THE telescope in question is to be sixty metres long, but no deformation of the image by flexure will be produced, as the telescope tube will be placed horizontally on the ground and the moon or star under examination reflected into the tube by the mirror referred to. There should be some record photographs of the moon taken by it, and the value of such photographs is well known, for the power of the instrument will be such as, in popular parlance, to bring the moon within a distance of thirty-six and a half miles.

**Preservation of Rubber Goods.**—Every one familiar with vulcanised rubber articles, chemical gloves, for development and so forth, is aware that they are liable to deterioration and, at times, to become absolutely useless if kept for some time without being used. A writer in a scientific contemporary states that he found that in the Western States of America, where the deteriorating action of time referred to seems to be intensified by the extremely dry condition of the atmosphere, it is the custom to keep such articles wholly immersed in weak ammonia solution.

**Deterioration of Aluminium.**—The use of aluminium in photography is mainly confined to lenses and fittings, though it has been recommended for dishes or trays for various operations of the dark room. A report presented to the French Academy of Sciences by M. Ditte some time ago tended to show that it is very unsuitable for all utensils intended to contain liquids, and, although his research more particularly referred to cooking utensils, it is obvious that similar results must obtain when the metal was employed for liquids in photographic processes. Thus, he found that weak acetic acid quickly acted upon, but water alone sufficed to dissolve, it. In the Madagascar expedition large tanks of aluminium were employed for storing ordinary drinking water in, and it was found that they quickly became pitted with holes. On the other hand, M. Moissan, a great authority on such questions, traverses M. Ditte's report. He points out that the aluminium vessels supplied were made in the early stage of the industry, in the working of that metal, and were very far from being pure aluminium, a condition of affairs known to greatly favour corrosion. M. Moissan also points out that this metal readily forms an electrolytic couple with almost any other metal, and that the pitting referred to was owing to undoubted electrical action the tank frames in contact with the aluminium thus setting up action that resulted in solution of the sides of the vessel. An interesting discussion took place between the two eminent authorities, the result being the conclusion that, so long as contact with the other metals was avoided, the use of pure aluminium for household or military utensils would not be attended with any possibility of danger or inconvenience.

#### JOTTINGS.

"To sit on rocks, to muse by flood and fell," borrowing a line from Byron—probably the greatest and most human poet of the century—has been an unrealisable ambition of mine all this blazing hot July; and in that ambition and the impossibility of gratifying it no doubt I have many, many companions. It has been too hot for anything but the application of Sydney Smith's formula, "Take off your flesh and sit in your bones." Some of us would have been glad of the opportunity of doing this at Gloucester. But—it could not be done. The man of all others whom I have pitied during the last few weeks has been the dark-room hand, whose duty it has been to develop 60, 70, 80, or 90 negatives of an afternoon and evening in an ammonia-laden atmosphere, with the thermometer at 80° or 90°. These things have been done; they must be done.

It has been hot work, too, in some of the studios for sitters and takers alike. Here is an idea: Some years ago, when we were blessed with a spell of warm, fine weather, performances of plays in the open air were revived, and ever since then they have been given at frequent intervals. Don't you think some of our advanced and aspiring young photographers might borrow a hint from this and institute open-air studios? What could be more delightful to a fashionable Belgravian maid or matron, clad in the choicest gown of her favourite *modiste* than the opportunity of having her portrait taken *en plein air* in some delightful old-world garden in the "old court suburb" of Kensington, or any other attractive part of London. What scope it would give for effects in lighting, posing, and natural backgrounds!

Too hot to talk, as well as to work. The great rush out of London has peopled the meeting rooms of the photographic societies with a beggarly array of empty benches *plus* a few dismal persons whom duty obliges to keep on the treadmill. The treadmill of honest labour is what I mean, of course. Even at the Camera Club, that charming home of photographic dilettantism, a man who could show any interest in practical photography during the last few weeks would be looked upon as a curiosity, a fitting object for the R.P.S. museum. And the great doors of the baronial halls in Russell-square are closed; the voice of the loquacious Councillor is hushed; the Exhibition Committee has ceased from troubling for the present, and the Hon. Secretary is at rest (*pro tem.*). So, even in those

haunts of photographers who, unlike my friend Mr. Cooke, prefer to talk rather than to do, the "L and P" and the Club, an almost monastic silence prevails. Everybody is doing nothing and nobody is doing anything.

Now, all this is what comes of a Convention at Gloucester. The languorous charm of the place seems to attach itself to you, if not to imbue you with its own irresistible subtlety. It appears to be always afternoon in the western city. I never met a courtlier, slower, sunnier, more contented set of people than these same Gloucesterians. I suppose it was contact with our mild-mannered hosts which was responsible for what I call an outbreak of "Ye-e-s-old-chap"-ishness (spoken with a *blasé* kind of drawl) amongst many Conventioneers, who on ordinary occasions are not given to affectations of this kind. However, this was the only flaw, if flaw it be, in an otherwise flawless week. The tale of Gloucester has already been fully told, and needs no retelling. Newcastle will keep till next year. Meanwhile may I make a suggestion to Gloucester Conventioneers? Many promises of prints were made a fortnight ago. For the credit of the Convention, and wherever practicable, let those promises be kept. It should be done.

A very old institution with exhibiting photographers has just died the death; I allude to the Royal Cornwall Polytechnic Exhibition at Falmouth, the photographic section of which will not be held this year, at any rate. Time was when a medal at Falmouth was deeply coveted by photographers of the highest eminence; and, in the early gelatine days, those firms upon whose plates prize pictures were taken were greatly elated at their success. Messrs. Wratten and Messrs. Fry, I believe, secured Falmouth medals, and held them in considerable esteem. It is to be hoped that the Exhibition will be revived in a staple form, as there is surely scope for an annual photographic display in the great tract of country to the south of Exeter. Perhaps my old friend, Mr. C. K. Rowe, who, I perceive, has been busy judging photographic competitions in Devonshire, might be of assistance in the matter.

"Secco" film is, I believe, on the point of appearing as a company, the prospectus already being in private circulation. There is such a vast demand for flexible films in photography, and Secco, what I have seen of it, is so good that there should be no difficulty in floating the company. I hear, too, that the Premo camera is to be made the subject of a flotation. For American-made cameras the English appetite appears to be insatiable. Why is it that our home manufacturers are so slow in putting down plant to turn out apparatus of this character? I think the American camera-makers deserve all the success they are meeting with; but it is a somewhat sombre reflection on British enterprise that, so far, nothing of the sort has been attempted this side of the Atlantic. If the English photographer seriously pondered upon the extent to which he is dependent on our friends the foreigners for the means of practising his art, he would blush at the sting his patriotism must constantly receive.

To those photographers whose eyes at this season of the year begin to turn towards the autumn exhibitions, and who have not made up their minds what kind of work to attempt for sending in, I am anxious to give a hint which I hope may be useful. It is this. Keep an eye on narrative or dramatic photography. Some years ago a great friend of mine, Mr. A. G. Tagliaferro, produced some really splendid work of this character. At his home, Malta, he had command of some incomparably plastic sitters, and by their aid and that of specially built up scenery he produced a series of narrative, genre, or dramatic photographs the like of which have not been produced by anybody save Rejlander. Tagliaferro's photographs each told a complete story as distinctly and clearly as Orchardson's pictures, and, in their way, were just as good. I don't know whether prints from his negatives are accessible, but, if they are, I advise the photographer who is weary of mud flats, sunsets, evenings, and architecture to carefully study them. They will reveal to him a new world of photographic possibilities.

The friends and others who have inquired after the Salon epitaph may like to know that, with all the love and affection of an author for a favourite child of his own creation, I have taken the MS. out of the bureau where I keep my most cherished productions, have touched up the lines here and there, and have made an addition or deletion where it seemed desirable to do so. The epitaph may be needed sooner than is generally anticipated, for I hear that some of the most prominent Salonites, who have for long held aloof from Pall Mall, propose exhibiting at the R.P.S. next autumn. Seriously, I am told that some important secessions are likely to take place from the Salon. I shall be very sorry if this has the effect of fatally weakening the institution at the critical age of seven years; still as some consolation to the trustees in bankruptcy, if they would like a photographic copy of the epitaph in gum bichromate—why, it shall be done.

COSMOS.

#### CONCERNING THE ACTION OF NASCENT SILVER IN THE PROCESS OF DEVELOPMENT.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

CERTAIN photographic processes, such as the silver intensification of a negative, the development of the latent image upon a collodion plate, and the development of a gelatine plate after fixation, depend upon the deposition of metallic silver from the developer upon the nascent silver present in the film, be the latter due to the direct action of light upon the sensitive collodion or gelatine (Silberkeim theory), or to the action of the developer (subhaloid theory). The building up of the latent image upon a dry plate is similarly explained by the developer reducing the unaltered silver bromide of the emulsion and depositing the silver upon the nascent particles which are already present.

Eder resorts to electro-chemical considerations for the explanation of such processes and thinks, with Lermontoff, that galvanic elements are formed by the particles of silver, the solution of silver salt, and the developing solution, which by their action deposit silver. But, as such elements cannot be formed, excepting under conditions unfulfilled in the cases in question, namely, that the solution of silver salt and developer shall not be mixed, but shall flow side by side around the silver particles, we must find some other explanation. This may be found in the following manner:—

According to one of Ostwald's well-known propositions, supersaturation must precede deposition from a homogeneous solution; consequently, in the cases referred to, there must first be a supersaturated solution of silver. This is brought about in the following manner: Developers are reducing agents, that is, substances which strive to become charged with positive ions. The reducing action of potassium ferrous oxalate depends upon the endeavour of the double negative ions of ferrous oxalate,  $\text{Fe}(\text{C}_2\text{O}_4)_2^{--}$ , to take up a positive charge and change themselves to single negative ferric-oxalate ions,  $\text{Fe}(\text{C}_2\text{O}_4)_2^-$ . These positive charges are taken from the silver ions in the process of development, because the endeavour of the metallic silver to pass into the ion condition is much weaker than that of the ferrous-oxalate ions to take up a positive charge. The potential of an electrode, which cannot be attacked, for a solution of potassium ferrous oxalate, is about  $-0.28\text{V}^*$ , whilst that of silver for silver nitrate is  $-1.05\text{V}^\dagger$ . Now as the active reducing ions deprive the silver ions of their charge, a supersaturated solution of silver of very slight concentration is formed in the fluid, and, according to an acknowledged principle, this supersaturation finds relief at those parts of the system where nascent silver exists. Should more be present, the silver precipitates itself preferably on rough surfaces and the like.

In support of the theory, that in developing a dry plate silver bromide is reduced, although unexposed and almost insoluble, Eder‡ cites an experiment, according to which a plate immersed in developer is said to be reduced at those portions where a silver wire has been brought in contact with it. But, notwithstanding many attempts, I have been unable to repeat this experiment, which has generally been considered of fundamental importance in the theory of development and frequently quoted. At first I tried in the manner described by Eder. Gelatine plates were immersed in the developer (potassium ferrous oxalate or pyrogallol) and,

\* Bancroft, *Zeitschrift für Phys. Chemie*, 14, 193 (1894).

† Neumann, *Zeitschrift für Phys. Chemie*, 14, 229 (1894).

‡ Sitzungsb. d. K. Akad. d. Wissensch. Mathem. Nat. u. w. Klass. Vienna, 1880, vol. lxxxi., 692. *Handbuch*, vol. ii. 47; vol. iii. 93.

under avoidance of pressure, pieces of silver wire and foil, of purest quality from the refinery, were placed upon them and the action of the developer was allowed to continue up to thirty minutes. I also coated some plates with emulsion containing small pieces of silver wire and foil, which had been previously frosted with nitric acid. The plates were dried and subjected in a similar manner to the developer. In none of the many experiments which I made was there any perceptible reduction where the silver and the emulsion were in contact.

The negative results of these experiments surprised me much, and I was at first inclined to infer that only the slightest quantity of silver could be set free and reduced in the process of development, and that the bulk of silver forming the negative was predetermined by the action of light. In this case the nascent-silver theory would lead one to expect that a plate fixed immediately after exposure would show a distinct negative image, and the subhaloid theory, that a similar plate could be developed with an ordinary developer without any silver. But, as neither is the case, only one supposition remains, namely, that the bulk of the silver forming the negative is in fact produced by reduction from the unaffected silver bromide. Abney's\* experiments concerning the reduction of unexposed silver bromide by an alkaline solution of pyrogallol are decidedly in favour of this supposition, likewise the same author's experiment showing that the image formed upon a plate wanting in density may be intensified by coating the same with bromide emulsion before or after development, and then subjecting it to the developer.

But what was the cause of the failure of the experiments to which I have referred? I believe that the explanation must be sought for in the probability of the silver being deposited upon the surface of the small pieces of metal, and that it could not be traced without exact measurement of the latter before and after the experiment. The conditions are different upon development of a dry plate, as in Abney's experiments. In this case the silver is deposited upon the very fine particles of nascent silver present in the film, and it is apparent that the amount of silver in this case will produce a marked intensification, whereas it could not be detected upon the surface of thick wire, &c.

According to the exact measurements made by Eder,† reduction spreads but slightly, in a lateral direction, in the unexposed parts of the emulsion. The spreading of a line, upon a plate free from fog, after thirty minutes' development, was 0.008 to 0.01 mm.; in the presence of fog lateral spreading was more marked and amounted to 0.02 to 0.03 mm. The remarkable difference in the activity of the nascent silver at the margin of separation between exposed and unexposed silver bromide becomes less surprising when we consider that the silver would naturally be deposited most, in a given unit of time, upon the largest surface of silver, or, in other words, upon that portion where most nascent silver was present. Take, for example, the image of a white square upon a black ground. The deposition of silver upon the nascent particles would decidedly increase the extent of their surface. The deposit would form mostly within the square and with constant acceleration, whilst intensification would proceed but slowly in the adjacent portions devoid of nascent silver. Similar facts may be observed in the analogous process of intensification with a developer containing silver.

Eder‡ found, when a plate was coated with a very thick, opaque emulsion of gelatino-bromide of silver, that reduction of the silver bromide in the exposed portions went completely through the film. Considering the very slight lateral spread of deposit, I differ from Eder, and believe that the penetration of development is not due to the action of nascent silver. I think it far more probable that most of the action is due to chemically active rays, notwithstanding the opacity of the film.

## PRINTING WITH BICHLORIDE OF MERCURY AND CITRATE, OR TARTRATE OF IRON AND AMMONIUM.

[Translated from the *Photographische Correspondenz*.]

In a similar manner to certain iron and silver processes, a paper prepared with arrowroot may be brushed over with a solution of bichloride of mercury and citrate of iron and ammonium. This printing paper when dry differs but little in appearance from silver nitrate and ammonio-citrate of iron paper (such as Arndt's and Troost's sepia flashlight copying paper).

When paper thus prepared is exposed to light under a negative, the exposed portions assume a brownish hue, and form a pale brown picture

upon a greenish ground. Upon immersion in water the unexposed image dissolves and a pale brown picture remains.

These prints yield a vigorous blue-black image, if they are well washed and treated with a suitable alkaline developer, especially if they are dried at a temperature of 80° to 90° C.

At first I was of opinion that in this process the reduction of the ferric to the ferrous salt by exposure to light converted the bichloride to subchloride of mercury (calomel), and that treatment with sulphite of soda (either at once or after washing) would produce a black mercurial image. This supposition was favoured by the behaviour of the print, which gained in intensity when treated, after washing, with dilute ammonia. It was also supported by the fact, that the image changed but little in the process of washing, whilst the bichloride of mercury and ammonio-citrate of iron were completely removed. On the other hand, treatment with sodic sulphite, after washing, did not produce any appreciable intensification of the original image.

It would therefore seem probable that the process which takes place when this mixture is exposed to light is the formation of a ferrous mercurous salt insoluble in water, which turns to brown basic salts by treatment with ammonia. Experiments also proved that this image can be intensified by alkaline development, the tones thus obtained being of a blue-black character.

The few experiments I have been able to make show that the process is deserving of notice, and I propose to continue them and publish the results at an early date.

Very promising results were obtained with the following preparation:—

A.	
Water.....	200 grammes.
Ammonio-citrate of iron (green) .....	40 „
Citric acid .....	4 „

B.	
Water.....	200 grammes.
Gelatine.....	6 „

These should be mixed warm, by yellow light, with

C.	
Alcohol .....	100 c. c.
Bichloride of mercury .....	24 grammes.

The paper should be brushed over with the warm solution, equalised and dried. Print under a vigorous negative.

The prints should be well washed, and after treatment with a solution of ammonia (5 to 100) and rewashing, developed with a normal developer (hydramine, for instance). The image soon assumes a vigorous brown tone, which changes to blue black when dry.

PROFESSOR E. VALENTA.

## TRICOLOUR TRANSPARENCIES FOR PROJECTION AND THE STEREOSCOPE.\*

### II.—THE PREPARATION AND COMBINATION OF THE SEPARATE IMAGES.

MANY methods have been suggested of preparing transparencies in any desired colour, but they are all based on the use of bichromated gelatine. Thirty years ago Ducos du Hauron prepared such pictures with carbon papers coated with gelatine, coloured with Berlin blue, carmine, orpiment, &c. In this process, however, the choice of colour is limited, as any colour cannot be used, and, moreover, differently coloured films do not print with equal gradations, so that pictures are obtained which differ considerably from one another, and the colour rendering of the finished picture is thus prejudicially affected.

It is much more convenient to prepare the pictures in gelatine free from colour and to colour them afterwards. They are then all of the same character, and it is possible to obtain any depth of colour by the use of aniline dyes, and it is possible to obtain the colours more or less saturated. The colouration is effected by immersing the picture in an aqueous solution of the dye.

The colourless gelatine images are obtained by a process very similar to the well-known pigment or carbon process, only that uncoloured bichromated gelatine is used; Lumière prefers a process similar to the bi-gum process, whilst Dr. Selle has worked out a process new in principle which is based on the different behaviour of exposed bichromated gelatine towards solutions of dyes.

The last two methods are protected by patent, but can be dispensed with, as the first process, which is founded on the carbon process, is quite satisfactory for small pictures, about which at the present we are talking. This method will therefore be described in detail, whilst those of Lumière and Selle will be briefly described.

\* Continued from page 410.

*A.—The Colourless Gelatine Images.*

As a support for the gelatine images only colourless absolutely transparent films must be used of a thickness of less than 0.1 mm. Gelatine, collodion, celluloid, and mica will give such films. For the method to be described the last two materials alone can be used.

Uncoloured bichromated gelatine films, such as were used by Vidal and later by Ives for the preparation of coloured pictures, have the disadvantage that the prints show a high relief, and therefore scarcely reproduce the details in the shadows.

This defect, however, can be easily got over by adding to the gelatine film a powder which stops the too deep penetration of the light during printing, and which can be removed again from the finished gelatine image. For this purpose silver bromide is the best thing, as it can be easily removed from the film by the aid of hyposulphite of soda.

The pigment process may be carried out in two different ways; either the thin image support, such as the celluloid or mica, may be coated with bichromated gelatine, and then printed from the back, that is, through the transparent support, and developed with warm water, or the film may be spread on paper and exposed under the negative, and the picture then developed upon the support in the usual way.

The first method is simpler and easier to carry out, and is specially useful when celluloid films are used; the second must be used when a somewhat thicker support, such as a sheet of glass, is considered desirable and absolute sharpness of the prints is essential.

*1st Method.—Direct Printing on Celluloid Films.*

Three-coloured pictures on celluloid films are obviously useful for the stereoscope, but they can hardly be used as lantern slides, as at a somewhat high temperature they suffer badly from cockling, &c.

The carrying out of this method has been rendered considerably easier by the rollable films, since, when sensitised in a solution of bichromate, they answer most satisfactorily for this purpose.

Pieces the size of the negatives are cut out of a spool of film always in the same direction, in order to avoid the expansion of the band of celluloid, which differs slightly in the length and the breadth. Celluloid is, according to its size, by no means a stable material; it expands considerably in water, and again contracts on drying, especially in hot weather, therefore it is only when the method of preparation is absolutely the same that the three prints can be obtained of the same size. The choice of the pieces for sensitising can be done, of course, as the silver bromide actually plays the part of a pigment.

The sensitising is effected in a solution of ammonium bichromate 1:80. The films should be completely immersed in the solution, and allowed to remain for about half an hour, and then hung up to dry.

Printing is done, as already mentioned, through the celluloid, so that this, and not the film of silver bromide, is placed next the negative. Printing should be done in the shade, and about five minutes' exposure is required.

After printing the pictures are developed with warm water, and this must be done slowly, and at as low a temperature as possible, in order to avoid any distortion through the softening of the celluloid. After development the film should be placed in a solution of hypo, to which a little potassium ferricyanide should be added, in order to remove any metallic silver which might be formed, and which would give a brown colour to the gelatine. The white silver bromide dissolves in the hypo, and an absolutely colourless gelatine picture is the result. This should now be washed with water, and the film placed, without drying, in the solution of dye.

*2nd Method.—Transfer Process for Pictures on Glass and Mica.*

This method is suitable, as already mentioned, specially for three-coloured pictures for projection. Sheets of mica, in the usual sizes of lantern pictures, of perfect quality, may be obtained commercially,\* so nothing stands in the way of its use.

It is not advisable, however, to prepare all the three images on this material, as the leaves break very easily, and are therefore difficult to handle, and their thickness, which is also increased by the gelatine, is rather troublesome. It is preferable, therefore, to make two pictures on glass, and the third on mica, and then to so combine the three that the mica is sandwiched between the two glasses. This procedure requires, however, that one of the two glass pictures should be reversed, so that this, when reversed, will have its film in contact with the other. This reversal of the image is most simply obtained by taking a reversed negative, by placing a sensitive plate in the dark slide with its glass towards the lens. This process is obviously easiest to do with the negative for the yellow print, whilst, in exposing for the blue and red, the sensitive plate should be placed in the correct position in the slide, and covered with the colour filter, whilst the ordinary plate without the filter is reversed in the slide. If the thickness of this plate is equal to each of the two filter plates, three negatives, which will absolutely correspond, will be obtained.

As previously mentioned, the negatives are printed on bichromated gelatino-bromide of silver paper, and then developed on the glass or mica plate.

\* From the mica warehouse of Max Raphael, Breslau.

For this a paper coated with ordinary silver-bromide emulsion should be used, and for a sheet 48×72 cm. there should be about 25 grains of gelatine and 20 grains of silver bromide.

The proportion between gelatine and bromide affects the character of the prints. For plucky negatives it is advisable to increase the silver bromide in order to prevent the formation of a high relief, whilst for soft negatives a paper poor in bromide should be chosen. The above quantities correspond approximately to the emulsion generally used for dry plates.

Any existing formula for such an emulsion can therefore be used; it should be washed in the usual way, then melted, and then coated on the same kind of paper as is used in the carbon process.

The preparation of the emulsion, as well as the coating and drying of the paper, can be done in daylight, as the silver bromide has only to act as a pigment and the grey discolouration caused by light does not matter.

The sensitising, printing, and development of the pictures is done exactly as in the carbon process, only, in order to obtain pictures of equal size, the following must be taken care of: The pieces of paper must be cut out of the sheet in the same direction, as the expansion caused by damp is different in the length and breadth of the sheet. Further, the prints must not, as usual, be soaked in cold water before squeegeeing on to the glass plate, but must be painted over on the film side with a broad brush with water, and then quickly squeegeed down on to the sheet of glass or mica.

In this way it is possible to obtain prints which will register every where, assuming that only small pictures are to be made.

After development in warm water the silver bromide is removed, as described above; the picture is then washed, and it can then be coloured.

**DEVELOPMENT WITHOUT LIGHT.**

THE increasing use of such plates as Cadett's spectrum and Lumière's panchromatic has lately directed attention to the quality of dark-room light which is safe to use with plates which are sensitive to almost all parts of the spectrum. Notwithstanding Messrs. Cadett's advice that their particular safe light must be used with their spectrum plates, I have for the last two seasons developed a large number of these plates without exposing them to light of any kind, timing the development by a modification of my well-known method of taking the time of the appearance of the image as a basis.

As I have lately received inquiries as to details of this method, consequent on my demonstration at the Convention, it may be convenient to give it for the benefit of all interested, especially as it does not of necessity require the purchase of any special apparatus.

*Outline of Method.*—A number of slips of the same brand of plate are provided beforehand, impressed with a standard amount of light. These slips are used for testing the developer before it is poured on the plate, and the time of appearance of the image on the slip is multiplied by a fixed number to give the time for the development of the negative. The negative is then developed in darkness for this time.

*Control of Results.*—It is a general idea that timing development is only suitable where exposures are absolutely correct and subjects do not vary much. This is not the case both in theory and practice. If a series of widely varying exposures on the same subject be timed in the way described, the negatives will differ in apparent density, the longest exposures being dense and taking long to print, and those nearest under-exposure thin and quick printing. Within certain limits, however (perhaps 1 to 16 with an average plate), all the negatives will yield prints of identical gradation. As regards variation of subject, I took out spectrum plates to Switzerland this year, exposing with the new Cadett light-filter on landscape, others without the filter, and also using the same plates for snap-shots, the variety of subject being great. All were developed without seeing results until fixed (using the same multiplying factor for all) with most satisfactory results.

If, at any time, it is desired to get greater contrast in the print, a longer multiplying factor will give it, or, if less contrast is required, a shorter factor can be used.

I have also lately found (somewhat contrary to my anticipations) that timing by the appearance of the image makes correct allowance for the density-giving capacity of various plates. For instance, I have taken six varieties of plates, some having a reputation for hardness, and some for giving soft negatives, and exposed them in proportion to their sensitiveness (previously found by the H. & D. method), and, on developing each for five times the appearance of the high lights with the same developer, the resulting negatives were practically identical. But let me proceed to describe the method which is specially suitable to colour sensitive plates, because it obviates any necessity of using a dark-room light at all.

*Details of Method.*—Mix the developer; I have used pyro soda, pyro 2 grains, soda 8 grains, bromide none. Turn down the gas (I am presuming the use of a room in darkness), take one of the trial slips out of its box, and, holding in a cycle clip, dip into developer in the measure, not moving about much. Commence counting seconds accurately as you dip the slip. At twenty seconds turn up the gas for an instant;

if the image has not appeared, turn down again and repeat a few seconds later. In this way the time of appearance of the slip is noted, or, if more convenient, it may be done in usual dark-room light. Suppose the image appeared in thirty seconds. With the developer named I got the gradation or contrast I like by developing for ten times. The negative will therefore require to be developed for ten times thirty, or for five minutes. All light is covered up or turned down, the plate put in the dish, developer poured on, commencing to count seconds at the same time, the dish covered up with a larger one inverted and the plate rocked. By the time three seconds is counted the gas can be turned up and the ekronometer set at half a minute past the starting point, or the watch looked at to note the time when the five minutes commenced. An occasional tilt can be given to the dish and at the end of the five minutes light turned down and the plate rinsed and put in a fixing bath. A little fogging of the trial slip is no harm if it does not come much before the image appears.

I have found great ease and comfort in using this plan of development with Lumière plates for Ives's kromskop negatives, being always sure of securing the same steepness of gradation, a most important point in colour work. For this work a shorter factor than for landscape work is desirable, as soft negatives with not too much contrast are wanted.

*The Trial Slips.*—A plate of the same brand as that to be used is placed behind a grating or screen in a printing frame and exposed to a standard candle at one meter for four times the inertia of the plate, as tested by the H. & D. method.

The plate can be of the largest convenient size, to be afterwards cut up into strips about  $1 \times \frac{1}{2}$  in. The screen is made by cutting lantern strips lengthways and pasting them diagonally on a glass plate, the opaque and clear divisions being equal.

As the inertia of a plate is found by dividing 34 by its H. & D. No.,  

$$\frac{34}{\text{H. \& D. No.}}$$
the number of seconds to expose the plate is—

It would be convenient that the maker who has already tested the speed of the plate should expose the trial plates to the same standard light and supply the strips in small boxes ready for use. I have found one plate last for a season's work. I am in hopes that these strips will be obtainable before long. The trial slip should be of the same brand as the plate developed, but it need not be the same batch of emulsion. I think this plan is a step in the direction of standardising photographic methods, for, so long as the same temperature is used to ascertain the H. & D. No. (which decides the exposure of the trial slip), a user of widely different brands of plates can develop each to exactly the same stage of gradation with the aid of its trial slip, and, as he has already (with the aid of the H. & D. No.) been able to give a relatively correct exposure, he can secure identical negatives on brands which have a reputation for widely different results. I have proved this by trial.

ALFRED WATKINS.

#### PRINTING FROM UNFIXED NEGATIVES.

HERR GOLDSCHMIDT, of Charlottenburg, in describing such a process, points out that in photographic practice it is usual to obtain a strong copy from thin, weak negatives by copying under silk paper, or, when the negative is very thin, under yellow glass or yellow-waxed taffetas or the like. Upon this principle the new process is based. The photograph is taken and the view is developed by means of a strong developer, but only to such an extent that, when examined, all the details are visible. The plate is then very rapidly washed, and, whilst still wet and in its unfixed condition, a sheet of bromide of silver paper, or a bromide of silver post card or other very sensitive copying paper, is placed and squeezed upon it by means of a rubber squeegee, and then, as in the usual copying process, in producing a so-called contact copy, exposed to the light of a lamp for a few seconds. The paper is then lifted off and developed in a suitable developer, and can be fixed and washed afterwards.

By omitting the fixing of the photographic plate, the yellow bromide of silver is preserved in the film and acts as the above-mentioned yellow veil in copying the thin negative, and by this means a clear, strong picture is obtained from the latter, notwithstanding its thinness, which renders it completely unfit for use in the ordinary way.

By proceeding in the above-described manner all the time is saved, as will be easily understood, which was formerly necessary for the washing of the negative, fixing it, and for thoroughly washing it again.

The application of the bromide of silver paper upon the non-fixed negative whilst wet is done not only in order to save time, but also to obtain, what in the dark can be judged of with difficulty, an intimate contact between the film and the bromide of silver paper. To attain the latter still more rapidly and completely, the bromide paper, prior to its application, may also be thoroughly moistened in water under the tap or by immersing it in a bowl of water, so that, on application of the paper to the plate, there is only water between the two layers, which is expelled by pressing the two together by means of a rubber squeegee.

In this way air bubbles are avoided, and the formation of spots resulting from the refraction of the light in copying is prevented.

The process above described allows of the production within less than

four minutes, as numerous tests have proved, or even within less than three minutes after taking the photograph, photographic positive pictures either on paper or on other material, and of producing, moreover, within a comparatively shorter time from the existing negative any desired number of copies.

In the last case it was found from time to time that a certain amount of developer, owing to the rapid washing of the plate, was still present though in a dilute condition in the negative film, and, under the action of the light necessary for copying, it gradually veiled the negative, so that, when a large number of copies were to be made, the last were not of so good a quality as those first made. This drawback is avoided by immersing the plate just developed, after having been rinsed for a few seconds, for some seconds in an aqueous solution of bromide of potassium, it being then again rinsed rapidly before printing. The solution of bromide of potassium remaining owing to the very rapid rinsing in the layer acts in the subsequent printing process not only not prejudicially, but contributes in bromide of silver paper to the production of a picture rich in contrasts and showing considerable density, whereby the decrease of power or loss of tone which always takes place with bromide paper during drying is compensated.

#### PLASTER CASTS FROM NEGATIVES AND POSITIVES.

HERR SCHUTTE, of Charlottenburg, proposes to accomplish the process here mentioned in the following manner:—

After having taken a particularly clear photograph of the object to be reproduced, which is best done on a plate coated with a thick layer of emulsion, the parts decomposed by the light are well washed after developing and fixing. Over the photographic plate, *a*, which has been treated in this manner, the frame, *b*, made of wood or other suitable material, is placed, the frame being so made that it covers the edge of the plate, *a*, slightly.

Into this frame a layer, *c*, of liquid plaster of Paris is then poured. As soon as the plaster has hardened a little, the frame, *b*, is removed, and the slab, *c*, of plaster of Paris is lifted off the photographic plate, *a*. The under side of the plaster slab, *c*, now shows the exact "relievo-like" reproduction of the photographic negative.

If it is desired to use this plaster cast directly, as medals, ornaments, or for any other purpose desired, it will be well to suitably colour the plastic side. The colouring should be done by water colours, and by means of a large and very soft brush. The colouring matter will collect principally in the sunk places, and thus an effective picture will be produced. By galvanoplastic means printing blocks, ornaments, &c, may be produced from the plaster slab, *c*, in the usual manner.

An analogous process has been protected by Herr Pietzner, of Vienna; here is his description of it:—

Equal parts of agar-agar (an alga—vegetable gelatine) and pure gelatine are dissolved in water just sufficient to dissolve the two kinds of glue into a viscid mass. This mass or substance is then mixed with a solution of three per cent. to eight per cent. chromate of potassium, according to the light and shade effects of the original (picture or body) which it is desired to photograph for sensitising purposes, and is then applied as thick as possible to a smooth glass plate, and dried with the exclusion of

light. The plates thus prepared are essentially suited for the production of reliefs, as they enable high reliefs of great resistance to be obtained, which are developed first in tepid water, then in warm water, and finally in water containing acetic acid.

From a negative photograph, taken in the ordinary manner from any desired original, is produced a positive high relief, by causing the gelatine to swell through the action of water thereon. From this positive a plaster of Paris cast is taken, which naturally must be negative, and to which in the following I will refer as the gypsum matrice.

Again, from the original there is produced a diapositive, and by means of this a high relief, which latter is therefore a negative, from which a plaster of Paris cast is made, this latter being a positive, and hereinafter called the gypsum die-plate.

Thereupon a thin layer of plastic clay, or other suitable material, is prepared, and pressed into the gypsum matrice so as to obtain a positive cast. The gypsum die-plate is now coated with shellac by preference, or other similar substance, and is afterwards corrected or touched up in accordance with the requirements of the art of plastic representation, without, however, paying too minute attention to a perfectly accurate likeness in every small detail of the original. This touching up is done by raising the portions that are too low or too deep by a covering with wax, or similar tough but plastic substance, while scraping the parts that protrude too much. The clay impression previously made by the aid of the gypsum matrice is then properly applied to the corrected gypsum die-plate, and gently pressed. This may also be effected by pressing the corrected gypsum die-plate on to the back of the clay impression contained in the matrice, so as to cause it to unite therewith or adhere thereto, and afterwards removing from the latter the clay together with the die-plate.

The clay impression thus transformed on to the gypsum die-plate is now no longer able to sink at those parts which in the first instance were too deep, because they are now resting upon the corrected die-plate. The combined clay impression and die-plate is then finally finished and touched up in the usual manner.

The chief characteristic feature of this improved process consists in that a gypsum die-plate, the main features of which resemble the original, and which die-plate is produced by any photographic or photo-mechanical means, and used in combination with a second positive impression of clay, or the like, also taken from the same original, for the purpose of enabling minute details of the original to be reproduced, and by the combination of the two parts to obtain a true and faultless plastic representation of the said original.

A second method of carrying out the afore-mentioned process is as follows:—

From a negative relief, produced by the aid of a diapositive, or by a gypsum matrice prepared from a positive relief obtained from a negative impression, there is produced a positive impression in a thin layer, the material used being plastilin, a plastic commercial article much used by sculptors, and resembling wax or putty; or, if desired, wax may be used when moulding direct from the original relief, while clay may be advantageously used for moulding from the gypsum matrice.

The impression, whether produced in plastilin, or wax, or in clay, by the one or the other means, is then, by means of a moulding board, worked and pressed home as usual, until the impression, from an artistic point of view, is fully equal to the original, and those parts which at first were too low are raised into their proper position. If found necessary, the cast may be retouched, as in the first process before described, so as to produce an artistically finished plastic model, from which, if desired, a mould (matrice) may be taken to serve in casting or otherwise forming the subjects or articles, hereinbefore referred to, required for the various branches of the industries.

If the articles are made of ceramic ware, they may, if desired, be produced in a single or a number of colours burnt in during the firing.

#### DR. EDER ON ADUROL.

Messrs. A. & M. ZIMMERMANN have handed us the following report on Adurol-Schering by Dr. Eder:

On May 27 the *Chemische Fabrik auf Actien* (vorm. E. Schering) Berlin, requested the Board of the Royal Imperial Graphic College and Institute to examine and report upon the correctness of the following claims for their developing product, Adurol-Schering. The following advantages were claimed for adurol over hydroquinone: firstly, as regards its power of development it stands between hydroquinone and the so-called rapid developers, metol, para-amidophenol, &c.; secondly, that adurol does not produce such a hard result as hydroquinone, and that with fully exposed plates it has an advantage over the rapid developers, in that development is much more easily controlled; thirdly, it is also claimed that adurol keeps indefinitely, and it has the further advantage over the rapid developers of superior solubility (due to its lightness), neither is there any need for caustic alkalies in stock solutions; fourthly, the ready-mixed developer does not turn brown through oxidation by contact with air, therefore solution can be used over and over again without fear of staining.

Conclusions: Schering's adurol is a bromide preparation of hydro-

quinone, i.e., "monobrom-hydroquinone." It occurs as a white crystalline powder, soluble in water, and even more so in alcohol and ether. As regards its properties as a developer for gelatine dry plates, trials were undertaken with this developer and with equivalent quantities of hydroquinone in connexion with the sensitometer in this laboratory, and also by practical proof in a studio.

The formulae used were those given by the manufacturers:—

#### I.—CONCENTRATED SOLUTION.

Pot. carb. ....	150 parts.
Soda sulphite cryst. ....	75 "
Water .....	200 "
Adurol .....	15 "

For use take 1 part of above and 10–15 parts of water.

#### II.—SEPARATE SOLUTIONS.

A. Soda sulphite cryst. ....	50 parts.
Water .....	500 "
Adurol .....	10 "
B. Pot. carb. ....	60 "
Water .....	500 "

For use A and B are mixed in equal parts.

The ordinary dry plates of commerce were used of the same make and sensitiveness (14–15 per cent. Scheiner and 23–24 per cent. Warnke). On testing two developers, one containing adurol and the other hydroquinone, in equivalent parts, the following results were arrived at:—

Under the same conditions of temperature, with adurol the pictures appeared quicker, and development was complete sooner than when using hydroquinone.

As regards speed, adurol resembles the rapid work of the para-amidophenol class. The high lights and shadows quickly appear, and the half-tones are built up little by little, while the finished picture is somewhat softer in graduation than that produced by hydroquinone.

A low temperature of the solutions had less effect on the working of adurol than on hydroquinone.

On the addition of potassium bromide to the solution so that it could be amply proved as claimed that potassium bromide delayed the appearance of the picture: In this direction it had a marked action, but the effect on the finished negative was insignificant as compared with that in the case of hydroquinone, pyro, or oxalate.

As regards the claim of point three we proved well founded that adurol-Schering, by virtue of its solubility, not only renders possible a concentrated solution which remains colourless for a long time, but also it easily succeeds in doing the work in the presence of sulphite of soda and carbonic alkalies without the aid of corrosive (caustic) alkalies.

It has only a slight tint, is of good-keeping qualities, and, when diluted with from ten to fifteen parts of water, gives a developer ready for immediate use, *vide* formulae (conc. sol.).

With hydroquinone it is not possible to make a similarly concentrated solution, it being necessary to dissolve by heat, and, when the solution cools, part of the developer was thrown out.

The ready-mixed adurol solution was used once and then kept in half-open bottles for fourteen days, becoming only slightly tinged, but remaining strong enough to produce a normal picture on an exposed dry plate.

In the practical trial in the studio it was evident that adurol was as suitable for portrait and instantaneous pictures as for landscapes.

The comparison with hydroquinone and metol gave the following results:—

Under the same exposure the picture appears with adurol in five to ten seconds, with hydroquinone in forty seconds, with metol in two to three seconds.

The development was finished with adurol in four to five minutes, with hydroquinone in six to seven minutes, with metol in about four minutes. The adurol deposit is of a beautiful grey-black colour, the density and the rendering of the fine details are very good.

These results worked out at this laboratory coincide exactly with the claims made above.

The sensitometer tests proved that adurol was twice as energetic as hydroquinone, and that hydroquinone (fresh) gave more developing fog than equivalent parts of adurol.

It has therefore been sufficiently proved that that product of Schering, commercially known as adurol-Schering, produces a developing solution with all the good properties of hydroquinone and many advantages, the picture appearing quicker without the presence of caustic alkalies, as were hitherto necessary. Further, it also works rather more softly than hydroquinone, and also that adurol is permanent as concentrated solution, and that this developer can be used over and over again and does not deteriorate.

In conclusion, it must be stated that adurol-Schering bears relation in its properties to the analogous chlorine derivative of hydroquinone known as adurol-Hauff, which emanates from Hauff & Co., in Fenerbach, and which, as commercially issued, is very similar, and gives practically the same results.

The Director of the Royal Imperial Graphic College and Institute.

Vienna, July 1, 1899.

(Signed) DR. EDER.

## REDUCTION AND INTENSIFICATION.

On the 17th inst. a Beginners' Evening was held at the North Middlesex Photographic Society, when Mr. J. McIntosh dealt with reduction and intensification. He said that most reducers, such as Howard Farmer's and Belitzki's, altered the ratios of gradation, as they acted more powerfully upon the shadow detail than upon the high lights. As an illustration, he suggested that, if a slice of sponge, the interstices of which were filled with crystalline matter such as candied sugar, were cemented to a sheet of glass, it would be an analogue to the gelatine film with the silver image imbedded in it of an ordinary negative. To bring the analogy closer, it was suggested that the crystalline matter in the sponge should be unequal in thickness, that a thin layer near the surface of the sponge would represent the shadow detail, that the half-tones would be represented by a layer of greater thickness, and that in the portion representing the high lights the thickness of crystals in the slice of sponge would reach down to the glass. He suggested that, if this imitation negative were immersed in warm water, the crystalline sugar all over the surface of the film would be rapidly dissolved out. Shadow, half-tone, and high light would be equally affected, but the relative action would be very different. The portion representing the shadow detail would be entirely removed, the half-tone would be reduced by, perhaps, only half its thickness, and of the high light possibly only one-eighth would be dissolved. The interstices of the sponge would be so filled up with syrupy matter that the water which acted as a solvent would be unable to act upon the crystals near the glass. In the actual negative the action was very similar. On the surface of the film the silver was dissolved by the chemical acting as the reducer, and passed freely into the bath, but in the half-tone and high lights the solution saturated with silver was held in the meshes of the gelatine, and protected from action the silver near the glass.

Recently a new agent had been introduced. This agent, ammonium persulphate, acted in a very different way. According to some authorities it dissolved away the high light to a greater extent than it did the shadow detail; according to others, and among these was Mr. John Sterry, the action was proportionate throughout; and the lecturer believed that this latter opinion was the correct one. The reason for this peculiar action did not appear to have been definitely decided. MM. Lumière and Seyewitz were of opinion that it acted most energetically in the presence of an excess of silver. Professor Namias demurred to this, and M. A. Hélain had advanced the theory that the gelatine in a negative parted with its hydrogen in proportion to the amount of silver bromide which was reduced to metallic silver during development, and that the ammonium persulphate acted upon the silver where the gelatine was oxidised, and upon the gelatine where it was in its normal state.

This theory might not prove to be absolutely correct, but it appeared to be a reasonable suggestion, and, if confirmed, supported Mr. Sterry's contention that the action was proportional.

In practice a two per cent. solution of the salt was a convenient strength for most work, and might conveniently be increased to five per cent. where the reduction required was great, and it had been suggested that a trace of sulphuric acid would assist the action. In working with strong solutions, particularly in warm weather, it was a useful precaution to saturate the solution with alum to prevent the solvent action of the chemical upon the gelatine.

When sufficient reduction had taken place, a whitish deposit would be found upon the portions most strongly affected. This compound of silver and sulphur would probably darken in light if not removed. To effect this, and to stop farther action of the ammonium persulphate, it was desirable to treat the negative with a five per cent. solution of sodium sulphite, or with the ordinary fixing bath (the lecturer preferred the latter).

In speaking of intensification, he said he had on previous occasions dealt with various intensifiers, and on that occasion would bring to the notice of the members of the Society the claims of Edwards's intensifier. This was a mercury compound, but, unlike most others, was a single-solution intensifier, and, in consequence, was particularly suited for local intensification in pictorial work, as the increase of density was seen as the action proceeded. The formula was:—

A. Mercuric chloride .....	60 grains.
Water .....	8 ounces.
B. Potassium iodide .....	180 grains.
Water .....	2 ounces.
C. Sodium hyposulphite .....	120 grains.
Water .....	2 ounces.

A was added to B and well shaken, and then C was added.

The solutions should be allowed to ripen for twenty-four hours before use. The results were not absolutely permanent, but, if fading took place, the negative could be restored by bathing in a five per cent. solution of Schlippe's salts. For general intensification over the surface of the negative, the plate was immersed in the solution, and allowed to remain till the required density was obtained, after which it should be thoroughly washed.

When slight increase of density only was required, the process was best suited to negatives which erred on the side of brilliancy, since it was

obvious that the action was from the surface downward, and the shadow detail would be fully intensified, while the half-tone and high lights would be only partially affected. When a flat negative had to be dealt with, the lecturer recommended the use of Monkhoven's intensifier as conferring greater brilliancy.

When local intensification was required he recommended that the plate should be first soaked in water, and then immersed in the solution till it assumed a brown tint and rinsed, after which the solution should be applied by a tuft of cotton-wool to those parts which required greater density. In the hands of a person who knew exactly what was required for pictorial purposes the process was capable of producing considerable improvement in the negative without interfering with the photographic detail or introducing inharmonious results.

## A PLEA FOR NON-PERMANENT PRINTS.

We take great pains to make our photographic prints as permanent as possible; if we thought more deeply over matters, we would not. That is, from the more important psychological point of view, for look for a moment at what permanent prints mean. In a world of change, and in which change means essentially vigour and life, we would have permanency in this photographic direction. But, as more to the special point, let an instance or two be taken. A woman has her photograph taken in a dress fashionably out, with her hair done up in the fashion in vogue. How long do the all-important accessories remain fashionable? And what is the photograph worth otherwise? Does not everything look absurdly antiquated in five years time? Does not the photographee tear up or burn any of the prints she may have in hand? And would she not give a good deal to be able to recall the ones distributed amongst her friends? What we evidently want here is not a permanent print, but one that fades with the fashion—one that, taken when bishop sleeves were the correct thing, will be but a blank when bishop sleeves have given way to something else. The same applies in a degree to a man, although not quite so markedly perhaps in the particular direction of dress, owing to the less range of change in it. But shape of collar, cut of whisker, style of trouser in his case are changeable enough to make a picture ten years old look very much older, and become correspondingly disagreeable to look at. Or, ignoring dress, if we can rise to such a height, who at heart likes, after he has passed forty, to think that he is getting older? By poetic right an old man should be satisfied with quiet autumn thoughts in the decline of life. But is he? Not he, nine times out of ten, but begrudges instead lusty manhood gone by. We feel, of course, with a diffused kind of consciousness, that we are getting older, but certainly do not want to be reminded of it by the abrupt knock-down blow of a photograph. The changes of life, again, short of old age, are so many and varied that what we regard as fixtures to-day are soon done away with, and gone to-morrow. What does the husband do with the photograph of his first wife after he shall have married his second, and, *vice versa* the widow with that of her first choice when she shall have chosen the second time? It is hardly the thing to burn them, and, turned with their faces to the wall, they would look altogether too obtrusive. They are gently put aside, probably in some odd quiet corner, but have a knack of turning right side up at a future moment to stir up emotion better let be. What a happy consummation had they but faded! How satisfactory to have escaped at the expense of the photographer! But the husband does not marry again, the widow remains a widow, and both probably do a good deal of sorrowful brooding over the past. Kindly nature does her best to dim remembrance and heal the wounds, all undoubtedly and admittedly for the best if the work of the world is to be carried on. Yet we do our best to counteract the beneficent order of things by keeping photographs in the most permanent materials, to be ever reminding ourselves of faces and joys long gone by and beyond recall. We cannot bring ourselves far enough out of the reach of sentiment and into that of reason to help by destroying the reminders. It is too much to expect from human nature; but how well would the circumstances of the case be met were photographs to gradually fade away at an equal pace with the mental picture and remembrance!

Leaving this side, where death and sorrow have had a hand in the printing and toning of feeling, the same desirability of fading remembrance is indicated by common sense as the better thing in many other directions. It has for instance been a feature of some magazines of late to give a kind of graduated ladder, as it were, of the growth of persons distinguished in arts, letters, or by high birth and social position, in a series of photographs of them from childhood up to the present time. An outsider may regard them as interesting after a fashion, but what must the one depicted, to whom after all the photographs must be the prime consideration, think of them? Personally any way—although there appears little likelihood of it at present—I should not care to pay such a penalty for being a well-known character. The posing, background, dress, accessories generally, of twenty or thirty years back, are far better buried, with all that made them appropriate enough at the time, but which are now sadly out of date. Pleasant pictures of

the past recorded on the brain are all very well, for they have become unconsciously modified and toned down by the all-round gradual changes in the medium they are printed in and on. A hard-and-fast photographic presentment, faithful in every detail, is a very different thing, and proof of it is clearly indicated by the jar experienced when such a one is unexpectedly presented to us. We would be happier without them; but, as we must needs be photographed, let it be in some of the less permanent processes.

The application of the principle is not confined to figures and portraits either, but will apply all round. The vividness of feeling that is correlated with the actuality of a photographic picture, other than a portrait, making it acceptable and pleasing when first seen is very short-lived. The sharpness of impression dies naturally away, the sharpness of detail of the photographic picture does not, and the two not being of a piece is why the leaves of albums are turned more quickly and carelessly over each time we look them over. There is, indeed, a luxury in the mind picture after the years have put in their effect upon it that is much detracted from by a photographic representation to compare it with. Take the pictures, for example, that most men carry in their minds of the distant scenes of their boyhood and youth, the house in the country, the square of the nearest small town, the wharf and they fished from, or what not. Photographs of these in thirty years' time, in clearing the haze that had gathered round them, and presenting them in their hard-and-fast, small, commonplace reality, do much to spoil the pleasure of their remembrance. They are worse than an actual visit to the spot, proverbially a pleasure-destroying proceeding, for the actual objects will have aged concurrently with their admirer and lover, and thereby gained something of mellowness, whereas a permanent print never ages. Then why have photographs at all? Because, on the other hand, there is a brisk, active present, full of detail which the photograph fits very well in with and is most admirably adapted for. Let us, if wise, confine our photographs to this, and, instead of aiming at permanence likely to become undesirable, try to gain command of a method of making a picture that will remain one as long only as we want it. Permanence in some directions is, doubtless, desirable, such as in the way of historic record for the benefit of those coming after, but, as an aid to individual human feeling and emotion, it is out of place.

This view will probably at a first glance be regarded as rank heresy by many, but it is due more to custom of thought than anything else. In proof of which let any photographer, who takes the trouble to think, look over his old prints, compare them as closely as he can with what he thought and felt at the time of taking and making them, and then with what he thinks and feels respecting the same places and people now. He will probably come to the conclusion that there is more in the contention for fleeting pictures than he thought when first presented to him.

A MINOR PHILOSOPHER.

## ON THE ACTION OF LIGHT ON THE SALTS OF COBALT.\*

### PART V. EXPERIMENTS WITH COBALTIC MALATE.

Moist cobaltic hydrate is sparingly soluble in an aqueous solution of malic acid on the application of heat. The solution of the malate thus produced is of a pale pink colour, and paper sensitised therewith is little, if at all, hygroscopic on drying. In sensitiveness to light, however, this salt is much inferior to the oxalate. Unsized paper, prepared by coating with a weak solution of the malate, failed to give any image on exposure to diffused light for over thirty-six hours. The addition of ammonium malate to the sensitiser occasioned no change in the character of the results.

The exposed strips were developed in a ferrocyanide bath, but this too failed to produce an image. On repeating the experiments, using instead of the ferrocyanide bath one of potassium ferricyanide, no change was visible so long as the bath remained neutral; but, on the addition of a few drops of acetic acid, a very faint bluish image appeared, noticeable only on those portions of the paper where the action of the light had been most intense. On the other hand, a ferricyanide bath, made feebly alkaline with ammonia, gave not the slightest image.

By using a more concentrated malate solution as a sensitiser it was found possible to obtain an image by development in a neutral ferricyanide bath, and this even when the exposure was considerably reduced. In one case a faint, but distinct, purple outline of the features of the picture was produced by such a bath after an exposure of only three hours in dull diffused light.

An attempt to develop, by means of mixed solutions of lead and mercurous nitrates, the latent picture produced by a ten-hours' exposure in diffused light was unsuccessful, no change being apparent.

The spectroscopic experiments made with this salt afforded results which at first sight are not altogether readily reconciled. The state of concentration of the sensitising solution would seem to have some influence on the character of these results, though it is perhaps doubtful whether the variations noted can be attributed entirely to that source. Seeing that, in one case at least, a secondary action manifested itself, and the image at first formed was gradually destroyed, the hypothesis

that a similar cross action may be assumed in the remaining cases, as a means of partially accounting for facts for which no other explanation offers itself, seems reasonable and, indeed, necessary.

The two prints first to be mentioned were made on paper sensitised with a moderately concentrated solution of the malate. In the other instances the solution employed for sensitising was much stronger, each fluid ounce containing upwards of seventy grains of the salt. The first print received an exposure of thirty-five hours to the rays of the spectrum. No change was visible until the paper was immersed in the usual ferricyanide bath, when a very weak reddish-brown image appeared. So far as could be judged, the maximum action seemed to be due to the violet rays. Considerable action appeared also to have been produced by the yellow rays, but the print as a whole was much too feeble to permit of an estimate being made of the relative intensities of the light at different parts of the spectrum. The next print was exposed for 100 hours. A greenish image was formed directly by "printing out," but the impression was exceedingly faint, and considerably obscured by superimposed yellow patches, representing an intermediate stage in a bleaching process, which was noticeable in the high lights. Decided proof of action in the green and the indigo rays was afforded by the print, and less decisive but sufficient evidence of action in the violet and the blue. On transferring it to the ferricyanide bath a plum-coloured image of quite a different

COBALTIC MALATE.

Fig. 11.

Fig. 12.

Fig. 13.

character was produced, represented in fig. 11. The position of the maximum deposit was now removed to the red rays, the green exercised only a weak influence, and the rays of greater refrangibility were apparently inoperative. In the third experiment the exposure was of twelve hours' duration. A greenish-yellow image was obtained readily by "printing out," in which the range of intensities was fairly well marked. Fig. 12 represents this image. It will be seen that the blue rays exercise the strongest influence and the red the least. There is also a deep depression in the region of the green rays, between which point and the less refrangible end a second inferior maximum appears in the orange portion of the spectrum. In the fourth experiment the exposure was increased to thirty-five hours. The image formed by "printing out" was now of an extremely feeble character, and quite different from that obtained in the former experiment, there being little signs of action elsewhere than under the yellow rays. On development in the ferricyanide bath a purple-red image was immediately produced, not so perfect in its gradation as the first (fig. 12), but still sufficiently vigorous to be capable of reproduction in facsimile. It is shown in fig. 13. The action is now strongest at the red end, the maximum lying in the orange. Midway between the green and the blue is a second point of actinic activity, whence, passing to the blue, there is a gradual falling off in the intensity, reaching a minimum dead level in the region of the indigo and violet rays. In the last experiment the print was exposed to light for ninety-five hours. This lengthy exposure failed, however, to produce an image by "printing out," another proof, if any were needed, of the gradual obliteration of the primary image by bleaching. On development in the ferricyanide bath the image flashed out in an instant, and speedily

\* Continued from p. 297, vol. 46.

obtained great vigour. Unfortunately, owing, no doubt, to the excessive exposure, the range of intensities was much obscured by the granularity of the red precipitate forming the image. However, the curious fact was sufficiently apparent that the blue rays had exercised the chief action—in other words, by increase of exposure, the image-producing influence had been transferred or displaced from the less to the more refrangible end of the spectrum. Hence there would appear to be two kinds of action to which the term secondary is properly to be applied, viz., (1) that which manifests itself by bleaching the image formed by "printing out," and (2) that which produces the displacement in the refrangibility of the chemically active rays of the spectrum that is, in certain circumstances, observable in the image produced by development.

#### EXPERIMENTS WITH COBALTIC FORMATE.

This salt is slightly sensitive to light, and may be prepared by dissolving cobaltic hydrate in warm dilute formic acid. So prepared, it forms a brownish-red solution, from which, on cooling, a portion of the hydrate is reprecipitated as a reddish mass. Paper sensitised with the cold clear solution of the formate was dried and duly exposed to light under a negative, but merely the barest outline of an image was produced, and that only after an exposure of from sixty to seventy hours' duration. The deposit was of a brownish-yellow colour, and was bleached by a further exposure of ten hours in sunlight. A feeble violet-red picture was obtained by developing this in the usual ferriocyanide bath. Four strips of the sensitised paper were then exposed in succession in the spectrum slide, the exposures lasting respectively 15, 65, 75, and 120 hours. In the case of the second experiment (exposure 65 hours) a faint orange band was produced by the impact of the yellow rays of the spectrum, but in the remaining experiments no image whatever was formed by "printing out." The exposed strips were successively developed in the ferriocyanide bath. The first gave a very faint brown image, in which the action of the light seemed to have been confined to the less refrangible portion of the spectrum, the maximum point lying in the yellow or the green rays. The second print gave an image almost identical with the foregoing. The third print instantly assumed a purple hue all over, and the true intensities were thus somewhat concealed. As before, however, the depth of the coloured deposit was more marked towards the red end of the spectrum, diminishing very evenly to a faint pink at the opposite end. The last print assumed a uniform but weak purple hue all over on being immersed in the developer, but a superimposed faint broad band in the yellow was also perceptible, as well as a narrow band in the blue, the latter, however, of exceeding feebleness. These experiments agree fairly well in serving to establish the conclusion that the disintegration of the formate is effected almost exclusively by the yellow rays of the spectrum.

#### THE WELLINGTON FILM.

A FORTNIGHT ago we made reference to a successful demonstration that had been given us of the new "dry" stripping film of Messrs. Wellington & Ward. We now append the principal instructions for the manipulation of the film, which is supported during exposure upon a paper backing. It may be exposed either in rolls or in cut sheets. After exposure, it is developed by any of the customary developing solutions, followed by an alum bath, and is fixed in the usual bath of hypo. When fixation is complete, the film is washed for a suitable time, and nothing more remains but to squeeze it down to dry upon a sheet of glass or ferrotype plate; after which, when dry, the film may be separated from the paper support.

The resulting film is flexible, possessing a fine matt surface, of sufficient body to stand rough handling, and may be protected against silver staining or humidity by being dipped bodily in any suitable varnish.

It is composed of no other substance whatever except the purest photographic gelatine. The entire support is thus as chemically inert, as regards the sensitive emulsion, as is the vehicle of the emulsion itself. Negatives upon the film may be printed from either side for carbon work or other processes in which such reversal is requisite. The matt surface lends itself well for retouching purposes.

As cut sheets the film may be employed in any dark slide, being backed up by cardboard, or other stiff material of sufficient thickness. The film may in like manner be used as cut sheets in any of the various forms of sheaths which are at present in usage for the purpose of holding celluloid film or negative paper.

The paper backing of the Wellington film is sufficiently translucent to permit the progress of development being judged in the usual way by holding up to the light. In this respect the new film resembles the negative paper formerly in use.

If desired, the exposed film may be soaked, before developing, in water for a few minutes until quite limp; it may be developed by any of the usual formulae. Messrs. Wellington & Ward, however, recommend pyro and ammonia for normal exposures, while pyro and soda is more suitable for instantaneous work.

#### PYRO AND AMMONIA (for Normal Exposures).

No. 1.	
Pyrogallic acid .....	1 ounce.
Sulphite soda .....	2 ounces.
Citric acid .....	40 grains.
Water to .....	10 ounces.

No. 2.	
Ammonia (880°) .....	1 ounce.
Water to .....	10 ounces.

No. 3.	
Potass bromide .....	1 ounce.
Water to .....	10 ounces.

Take 10 minims of No. 1 }  
 10 " " No. 2 } To each ounce of water.  
 5 " " No. 3 }

#### PYRO AND SODA.

No. 1.	
Pyrogallic acid .....	1 ounce.
Sulphite soda .....	2 ounces.
Citric acid .....	40 grains.
Water to .....	10 ounces.

No. 2.	
Carbonate soda .....	8 ounces.
Sulphite soda .....	8 "
Potass bromide .....	40 grains.
Water to .....	80 ounces.

Take 1 ounce No. 2; 1 drachm No. 1; Water, 2 ounces.

Negatives developed with ammonia strip perfectly from the paper support, whilst those developed with soda have a tendency to adhere more firmly; in some cases, if too much soda has been used in forcing, and through prolonged development the film may refuse to strip at all, this being caused by the alkali softening the gelatine and the paper so much that greater adhesion takes place between the two during drying.

No more soda should be used than is given in the formula.

*Alum Bath.*—Indispensable for preventing the curling up of the films during the after-process of washing. After developing, wash the negative in the usual manner. When freed from all traces of the developer, the film should be immersed in the following for fifteen minutes:—

Alum (ordinary) .....	2 ounces.
Water .....	40 "

*Fixing.*—The film must now be well washed and fixed in the following acid hypo bath, where it should remain for thirty minutes, taking care to turn them over from time to time to prevent unequal fixation.

No. 1.	
Hypo .....	1 pound.
Water to .....	70 ounces.

No. 2.	
Sulphite soda .....	2 ounces.
Sulphuric or acetic acid .....	2 drachms.
Water .....	10 ounces.

Mix by pouring No. 2 into No. 1.

*Washing.*—On removing from the fixing bath, wash in running water for about one hour.

The Wellington films have no tendency to damage one another by abrasion during the process of washing. The films still adhering to the paper support should now, without any further treatment, be squeezed to a ferrotype or glass plate (which has been thoroughly well cleaned with ammonia, whiting, and water, and, when quite dry, dust over the surface a little powdered French chalk, polishing off lightly with a dry cloth), allow to dry slowly in a cool place. It is advisable not to expose the film to the hot rays of the sun or to artificial heat, otherwise the film may become detached from the plate in the course of drying, thereby producing a wrinkled and cockled film. When dry, the film will easily detach itself from the glass plate.

No glycerine or spirit bath should be used, as after such treatment the films refuse to strip.

*Stripping.*—This process is, indeed, not absolutely necessary, since, if the paper backing be allowed to remain, the resulting negative may be printed in the same way as was customary with the old paper negative; but, inasmuch as most operators will prefer to have a negative which is translucent and prints as rapidly as glass, the exceedingly simple process of stripping will generally be adopted. Before proceeding to strip, make sure that the film is perfectly dry. Greater flatness will be secured by keeping the negatives a short time under pressure previous to stripping. The stripping of the film from the paper support

may then be conveniently started by cutting across one of the corners, film side up, with a sharp knife sufficiently to cut through the gelatine film only; then, by inserting the point of the knife between the film and paper, the two will be found to easily separate; now, with the back of the blade, loosen the film round the four sides. By gently pulling the transparent film from one corner, it will be found to easily leave the paper.

**Varnishing.**—For the prevention of silver staining, as well as to obviate any of the evil effects of dampness, the dried film may be conveniently varnished by dipping bodily into any suitable varnish which requires no heat, such as celluloid.

Sufficient varnish should be poured out into a flat dish, into which a single film should be immersed; lift carefully by two corners, allow to drain, and pin up to dry.

### THE "KROMAZ."

THE Kromaz is a system of colour photography enabling one to prepare transparencies, which, when viewed binocularly, show the object not only in relief, but also in colour. It is obvious, therefore, that between this system and the kromoskop method there is some analogy of principle, but it will be seen from the following description that the Kromaz differs greatly in detail from the older system:—

A—Set of colour screens in frame.

B—Repeating back, fitting into camera and taking half-plate slide, with screens in position.

C—Stereoscope for viewing photographs in colour.

The colour records consist of two pairs of images, which are produced by two exposures only in a single lens camera, the double image being secured in each case by means of mirrors. Of the first pair one image is given by the blue, the other by the red, and of the second pair both images are given by the green. Each pair is secured simultaneously; thus, the red and the blue are given together by the first exposure, and the two greens by the second.

The four images are all taken upon one half-plate, which is developed and fixed in the ordinary way.

The Kromaz back consists of a frame so designed as to be capable of easy adaptation to almost any front-focussing half-plate camera, by means of the dark-slide grooves. When fixed ready for use, the two square apertures are immediately behind the lens, and over them in parallel grooves the dark slide moves in such a way as to permit of the two halves of the plate being exposed in succession.

When the negative has been developed, fixed, and dried, a positive is taken from it, and this positive, when cut and mounted, constitutes the chromogram and may be viewed in the chromo-stereoscope.

The following extracts from the instructions will put the reader in possession of an outline of the plan of working the Kromaz:—

The three screens (one of them, the green, being double or stereoscopic) are arranged together in a frame which fastens on an ordinary half-plate dark slide, so that when the Kromaz back is fixed on the camera ready for taking, and the dark-slide shutter is withdrawn, the image from the lens can only reach the sensitive plate after passing through one or other of the colour screens, which robs it of all but the particular colour required to be registered at the exposure in question.

The back can be attached to almost any front-focussing half-plate camera.

A plate sensitive to all the colours of the spectrum is necessary.

These plates should be put in the dark slide in almost total darkness, as, owing to their sensitiveness to red, they would be quickly fogged by the ordinary ruby light of the developing room.

In the Lumière panchromatic or Cadett spectrum we have a plate sensitive to all the colours of the spectrum, but not in an equal degree, for the red and the green require to act on the plate several times as long as the blue to secure their proper effect. A fair average ratio of exposure

for the three colours is blue, 1; red, 10; green, 7; but by the Kromaz system the red and blue are paired and given the same exposure, and this is accomplished by slowing down the blue to the red by cutting off a large proportion of light with an orthochromatic screen.

**Making the Positive.**—Much of the success of the final result depends upon the quality of the positive taken from the negative.

The simplest way to obtain it is by contact printing in a printing frame. A Cadett photo-mechanical plate gives excellent results, the most convenient light being that given by an ordinary candle; the frame should be held about thirty inches from the flame and waved about slightly—the exposure of from two to three and half minutes according to the density of the negative is longer than that required when using a gas flame or daylight, but it is much more reliable, and a good positive can be obtained with greater certainty than by other means. *Development must not be too quick*, use a weakened solution of the developer, and aim at producing softness of image with long gradation.

**Cutting and Mounting of Positives.**—Before cutting the positive for mounting, hold it up to the light and place one of the mounts over a pair of the pictures. Mark the film at the outer edges of the mount, then lay the positive on a table and cut the film right across, but slightly smaller than the outside size of the mount; this is done to prevent any danger of the film dragging away from the glass when the latter is broken after being cut with a diamond or glass-cutter; it also serves as a convenient guide when cutting the glass.

To mount the positives, first take the pair of green images and lay it, film downwards, upon the mount, securing it with gummed slips of paper. Then, after it has been set aside for a few minutes to dry, slide it into the back of the Kromaz, film outwards, and push it as far as it will go. Next take the second mount and put it over the coloured screens on the top of the Kromaz, push it as far to the back and to the left as it will go, and then drop the remaining pair of images, film downwards, upon it. Shut the right eye and move the glass (not the mount) until the blue image falls exactly over the green, and colour fringes cease to be visible, then superimpose the red image in the same way, and finally secure the glass to the mount as before. If, when the chromograms are dry, it is found that they have altered slightly and the images in the Kromaz will not quite superimpose, the mounts may be filed at the edges until correct registration is obtained.

We have examined a number of results produced in the Kromaz, and found them exceedingly good. The Kromaz appears to be a simple and easily acquired method of producing stereoscopic transparencies in colours, and will, doubtless, be popular.

## Our Editorial Table.

### THE RAY CAMERAS.

A SELECTION of these handy little cameras of American manufacture has been shown us. One of them, Series No. 7, is adapted for tele-photo work, having a considerable range of focus. It has been especially designed for the convertible anastigmat, or lenses with variable foci. It is constructed with an auxiliary bed, which can be racked out over the ordinary bed to almost its entire length, giving a variation of focus in the 4×5 size of from 4½ to 12 inches, and in the 5×7 size from 5 to 15 inches. The auxiliary bed is made of aluminium, so formed as to make it extremely rigid, and its highly polished surface, in contrast with the

polished and lacquered brass, and mahogany finish, makes it an extremely attractive and elegantly finished camera. The other feature is the reversible back, by means of which pictures can be taken vertically or horizontally without changing the position of the camera on the tripod. It is also provided with swing back, rising and sliding front.

Series No. 2 is the tourist or cycle folding camera. A rack-and-pinion focussing attachment makes it very desirable for fine focussing, also a sliding front movement will be found convenient in making vertical pictures. The detachable lens board is a handy arrangement, whereby the shutter and lens can be removed and a wide-angle or any other lens inserted in an instant, thus doing away with unscrewing the shutter,

whereby the fine mechanism is often injured, and the annoyance caused by different-sized lens flanges is avoided. Extra duplicate lens boards can be secured at any time and fitted to any lens it is desirable to use in the camera.

A typical specification of the Ray Camera, that of Series No. 7, is as follows: (1) Polished mahogany case, bed and front; (2) Covering, fine morocco grain leather; (3) Bellows, fine maroon, extra long; (4) Trimmings, polished and lacquered brass and aluminium; (5) View-finder, brass top; (6) Rising and falling front; (7) Time, instantaneous, finger and pneumatic release shutter; (8) Iris diaphragm; (9) Sole leather carrying case; (10) Ground glass and focussing scale; (11) One tripod nut; (12) Leather handle; (13) One double holder; (14) Sliding front; (15) Detachable lens board; (16) Aluminium auxiliary bed; (17) Double rack-and-pinion focussing attachment; (18) Swing back; (19) Plate-holder adapter; (20) Reversible back.

#### CONVENTION PHOTOGRAPHS.

MR. W. D. WELFORD, of 19, Southampton-buildings, Chancery-lane, W.C., is good enough to send us half-a-dozen snap-shots taken during Convention week at Gloucester. They include clever and characteristic portraits of Mr. Bridge, Mr. Dugdale, Mr. E. Banks, Mr. E. J. Humphery, Mr. S. B. Webber, Mr. A. Seaman, and others, and in one of the groups it is alleged that the President-Elect is depicted giving utterance to the phrase, "It shall be done." We shall prize Mr. Welford's excellent photographs as souvenirs of a most enjoyable meeting.

PROMPT, as usual, to seize the opportunity of the moment, Mr. W. F. Slater, of 5, Firs-parade, High-road, Lee, S.E., has sent us a nicely framed copy of the Convention group. The frame is in Mr. Slater's best style, being of an elegant design, in wood, of a delicately tinted green. Mr. Slater's frames are always good and tasteful, and this one is no exception to the rule.

#### SPECIMENS OF ENLARGING, TRADE PRINTING, &c.

The Maxwell General and Photographic Illustrating Company, 44, Hatton-garden, E.C.

THE Maxwell Company undertake photographic printing, enlarging, developing, mounting, finishing, retouching, and lantern-slide making. Some of their enlarging work was on view at the Convention, and we have since had an opportunity of more closely examining a number of the specimens. These, upon inspection, show the work to be of a very high order of merit, both pictorially and technically, rich blacks and pure whites characterising the results. We wish the new Company success. On the occasion of the Convention excursion to Tewkesbury a cinematographic picture of the members leaving the boat was taken by a representative of the Company. A portion of the film has been shown us, and we perceive that it contains a number of easily recognisable portraits of prominent Conventioners.

DIE LICHTPAUSVERFAHREN, DIE PLATINOTYPIE UND VERSCHIEDENE COPIRVERFAHREN OHNE SILBERSALZE.

DIE PHOTOGRAPHISCHEN COPIRVERFAHREN MITTELS MANGAN-, COBALT-, CERIUM-, VANADIUM-, BLEI-, UND ZINN-SALZEN UND ASPHALT.

Wilhelm Knapp, Halle a/S.

THESE two publications form Parts 2 and 4 of Vol. IV. of Dr. J. M. Eder's *Ausführliches Handbuch der Photographie*, second edition. Both books are characterised by the same careful and complete compilation which Dr. Eder has exhibited throughout this standard work. The chapters on platinotype will, doubtless, be welcome to many whose attention has again been directed to the process by recent developments, and those in search of novel effects of colour may consult with advantage the details of the manganese processes given in Part 4. It is much to be regretted that an English translation of Dr. Eder's work has not been made.

WE have received an advance press copy of the Great Eastern Railway Company's *Tourist Guide to the Continent*, published at 30, Fleet-street, at the price of 6d. Among its fresh features are particulars of the new express service to Norway, Denmark, and Sweden, *via* the Royal Mail Harwich-Hook of Holland Route; of new tours in the Luther Country, and Thuringian and Hartz Mountains, a series of Continental maps, and a chapter, "Dull, Useful Information," giving particulars as to the cost of Continental travel.

#### CATALOGUES RECEIVED.

Isenthal, Potzler & Co., 85, Mortimer-street, Cavendish-square, W.

THIS catalogue has been compiled for the use of those who make the application of the principles of radiography a practical study. Induction

coils, tubes, screens and fluoroscopes, plates and films, accumulators and storage batteries are freely illustrated and described, and the radiographer will thus find the catalogue of the very greatest service to him. It is sent out at a charge of threepence.

McGhie & Co., 75, St. Vincent-street, Glasgow.

THE latest catalogue of Messrs. McGhie is an extremely well-printed production of over one hundred and fifty pages. There are between two and three hundred illustrations, and the catalogue appears to completely cover the ever-widening field of photographic supplies. It appeals alike to professionals and amateurs.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, August 2, at eight o'clock. Demonstration of Kachin by Messrs. Griffin & Son.

THE South London Photographic Society's Third Continental Excursion to Belgium takes place August 19-27. The leaders are Messrs. William F. Slater, F.R.P.S., and Walter D. Welford, F.R.P.S. The estimated total cost is 3*l.* 16*s.*, including saloon on boat. Any further particulars may be obtained from Messrs. William F. Slater, 5, Firs-parade, High-road, Lee, London, S.E.; and Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.

THE ARTISTS' GUILD.—Princess Christian offers prizes for embroidery at the Eleventh Amateur Art Exhibition of the Artists' Guild, to be held at the Royal Albert Hall in November. Prizes are also offered for painting, carving, photography, and work in leather and metals, &c. The competition is open to all amateurs. By special desire of Her Royal Highness, the Exhibition will be enlarged by a Section for Advanced Art, open to skilled artists, professional or otherwise. Particulars will be sent, on receipt of a stamped and addressed envelope, by the Secretary, the Artists' Guild, Exhibition-road, S.W.

ON Friday last week the staff of the Platinotype Company had their annual excursion to Folkestone. The weather was perfect, and a party of about ninety ladies and gentlemen reached the beautiful Kentish watering-place at an early hour. Carriage excursions to Hythe and neighbourhood were made both in the morning and afternoon, and a number of old English games were indulged in. Mr. E. J. Humphery presided at the luncheon at the Queen's Hotel, Folkestone, and he was supported by among others, Mr. Willis, Mr. W. H. Smith, Mr. Bedding, Mr. Wall, &c. After tea the party returned to town, obviously well pleased with a delightful day's outing.

THE Croydon Camera Club's Third Exhibition will be held at the Art Gallery, Park-lane, Croydon, on Wednesday, Thursday, Friday, Saturday, Monday, and Tuesday, October 18 to 24, 1899. The Judges are Mr. A. Horsley Hinton, Rev. F. C. Lambert, and Mr. Percy S. Lankester. The following are the Open Classes: H, Champion Class, pictures which have previously received an award, gold medal; I, pictures which have not received any award or certificate, silver and bronze medals; J, any subject, open to amateur photographers resident in the borough of Croydon, gold, silver, and bronze medals; K, lantern slides, set of six, silver and bronze medals; L, stereoscopic prints and transparencies, set of four, silver medal; M, not for competition, exhibits invited. Entry forms and further particulars can be obtained from the Hon. Secretary, Mr. W. H. Rogers, 106, Holmesdale-road, South Norwood.

MR. ALDERMAN G. P. WOODRUFF, J.P. (Mayor of Hove and President of the Hove Camera Club), in order to encourage artistic photography, has offered the sum of 5*l.* 10*s.* for prizes in a competition to be open to those only who have not previously taken an award of any kind in photography. The principal conditions are as follows: The prizes will be in photographic goods at Williamson's Stores, Western-road, Hove, and the winners will select whatever they wish to the value of first prize, 3*l.*; second prize, 1*l.* 10*s.*; third prize, 1*l.*. Only those amateur photographers who are members of the Hove Camera Club or reside in the town of Hove, and have not previously gained an award in any photographic competition, either open, club, or otherwise, will be allowed to compete. The entry forms must be sent in by September 21, and prints on or before September 26, 1899, to the Hon. Secretary, Mr. C. Berrington Stoner, 24, Holland-road, Hove.

THE Executive Committee of the Affiliation of Photographic Societies held a meeting at No. 68, Russell-square, W.C., on Thursday, July 13, Mr. G. Scamell (Hon. Treasurer) in the chair. The following lectures, with the authors' names as appended, were arranged for, and they will be ready for circulation, it is expected, by October 1: "Elementary Chemistry for Photographers," by Mr. C. F. Townsend; "Orthochromatic Photography," by Mr. E. Sanger Shepherd. Negotiations were opened for three lectures on the following topics: "Practical Photography in the Field," "Printing Dodges," "Photography by Artificial Light." It was arranged that, during the summer months, those of the old series of lectures which were not booked should be withdrawn for revision and set in order for the coming winter session. An offer from the Toronto Camera Club of a set of slides representative of Canadian work was accepted by the Committee, and it is hoped to have the set in circulation by the end of the autumn season. It was also agreed to exchange a set of slides by British workers with the American Lantern-slide Interchange in return for a similar set by American workers.

A FIRE broke out last week in the cellar of the premises of Mr. Andrew Baird, scientific-instrument maker and chemical dealer, 37 and 39, Lothian-street, Edinburgh. The outbreak was discovered shortly after two o'clock by a passer-by, who observed smoke issuing from the grating underneath the shop, and he at once ran to the Royal Infirmary and put himself in communication with the fire office. A couple of steamers were soon on the spot, but the firemen found themselves confronted with a difficult and even dangerous task. It was naturally assumed that a large quantity of chemicals were stored in the cellar, but as to the nature of the stuff, and consequently the exact danger of their position, the firemen were totally ignorant. To add to the difficulty of the work, the fumes from the cellar were so overpowering that it was impossible to get at the seat of the fire, and Mr. Portage had to break up the pavement before he could find access to the cellar. A number of alarming enough explosions took place, but the fire was extinguished before anything of a very serious nature occurred. A large case of methylated spirits and a quantity of ether were afterwards discovered, which the fire had fortunately not reached. The fire was regarded as of such a serious character that it was deemed advisable to remove all the families living in the tenement above the premises. Although occurring at such an early hour, a large crowd collected.

THE following is the list of winners in the Warwick Monthly Competition:—104 prize, *Interior of Lucerne Cathedral*, Mr. J. C. Oliver, 2, Royal-terrace, Glasgow; 51. prize, *Lady Standing before Window*, Mr. G. Speight, photographer, Market Harborough; 11. prizes, *Threshing Corn with Cattle in the Swat Valley*, Mr. W. P. Murray, 21st Punjab Infantry, Malakand Force, India; *Snap-shots of Barnum's Procession*, Mr. W. Wilkinson, Erwen-road, Colwyn-bay; *Sir Evelyn Wood Reviewing the Sandhurst Cadets*, Mr. G. E. Clarke, photographer, Camberley; *Open Door, Stanwell Church*, Mr. Hilton Grundy, Brentford, Middlesex; *In Cassiobury Park*, Mr. A. G. Lawson, 32, Ashley-road, Crouch-hill, N.; *Waiting*, Mr. J. T. Hall, engineer, London-road, Staines; *Snap-shot of a Game of Tennis*, Mr. G. L. Lavender, Aldridge, Staffs; *The Nave Chester Cathedral*, Mr. F. W. Knowles, photographic dealer, Warrington; *Pleasant Pastures*, Mr. J. W. Mills, 24, Clifton-street, Warrington; *A Thames-side Village*, Mr. H. E. Davis, Camera Club, London, W.C.; *On the Sands at Margate*, Mr. James Dee, photographer, Earley, Reading; *The Pets—Girl, Donkey, and Dog*, Mr. Henry Neville, 81, Revidge-road, Blackburn; *Copy from Water-colour Painting*, Mr. H. F. Hadland, 14, Gooding-road, Holloway, N.; *Portrait of a Boy Reading Paper in a Chair*, Mr. Herbert Kay, 1, Premier-street, Brooks Bar, Manchester; *The Ancestor*, Mr. J. H. Edwards, 101, Newhall-street, Birmingham; *An Irish Donkey Cart*, Mr. F. J. R. Macfadyen, The Gables, Monkseaton; *Washing Sheep*, Miss G. A. Jones, Stanington Vicarage, Cramlington; *A Corner of a Quay*, Mrs. Norman Macdonald, Coll, Earn, Auchterarder; *White Rhododendrons Growing*, Mrs. Ford, Quarrydene, Westwood, Leeds; *Young Girl Standing in Light Dress*, Madame Marie Weale, photographer, Helios Studio, Nuneaton.

## Patent News.

THE following applications for Patents were made between July 10 and July 15, 1899:—

CAMERAS FOR COLOUR PHOTOGRAPHY.—No. 14,364. "An Improvement in Cameras for Colour Photography." A. J. O. POLLOCK.

PANORAMIC CAMERAS.—No. 14,548. "Improvements in Panoramic Cameras." Complete specification. C. H. SHAW.

SENSITIVE PLATE-HOLDERS.—No. 14,563. "Improvements in Holders and Envelopes for Sensitive Photo Plates." P. WALLIS and E. F. WALLIS.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
1.....	Hackney.....	Open Night.
1.....	Oldham.....	Excursion: Prestbury. Leader, J. T. Whitehead.
2.....	Photographic Club.....	Demonstration: Kachin. Messrs. Griffin & Son.
2.....	West Surrey.....	Demonstration: Sensitising Paper. J. Bulbeck.
3.....	Hackney.....	Excursion: Christ's Hospital (Interior) Leader, H. J. Webb.
5.....	Ashton-under-Lyne.....	Excursion: Worsley. Leader, W. Greenwood.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 20.—Mr. R. P. Drage in the chair.

The CHAIRMAN said it was his pleasant privilege to hand to Mr. T. E. Freshwater, the late Secretary, a testimonial from the members, which, it would be remembered, was initiated at the very enjoyable outing which they had at Mr. A. L. Henderson's home at Brimsdown. He had great pleasure in testifying to the worth of Mr. Freshwater, and could speak, from personal acquaintance with the office of Secretary, to the fact that the Society owed a great deal to him for its present position. He still hoped that, though leaving

the Society in an official position, Mr. Freshwater would long continue to give his aid and support to the Association, and, with a firm trust in this conviction, he formally presented to the retiring officer a handsome timepiece, suitably adorned with an engraved inscription.

Mr. PHILIP EVERITT, who carried out the duties of collector on behalf of the fund, supported the Chairman's eulogy of Mr. Freshwater, who afterwards replied and thanked the members for their present.

Mr. J. E. HODD detailed some trials of ammonium persulphate which he had recently been making, and took the opportunity of protesting against the scant directions which the vendors saw fit to issue with this salt. He had been reducing with a three per cent. solution, and got every effect expected except that, after washing, the plate was covered with blisters. These he endeavoured to lay down with spirit and by pricking, but was desirous of learning whether the same fault had been observed by others. He explained that he had not soaked the plates for long, they were only washed for about half an hour, and that in running water. The persulphate solution was quite fresh.

Mr. J. S. TRAPE, as one who had had some experience with the new reducer, said he could not account for it. He had noticed, however, that the solution in four per cent. strength or thereabouts had a distinct solvent action upon gelatine, half an hour's sojourn therein being enough to dissolve away about half of the quantity of the gelatine which was on the plate.

Mr. P. EVERITT said that Liesegang had remarked upon the effect of and used old solutions as a means of dissolving away parts of the gelatine in order to get an image in relief. An acid solution would probably have the same effect.

Mr. HODD said that he noticed that the solution turned cloudy on the introduction of the plate.

Mr. J. A. SINCLAIR said he believed this was usually the case.

Mr. EVERITT said it was general knowledge that different samples had been found to act differently upon the silver image. Reverting to the observations of Liesegang, he said that, after the publication of his conclusions, Colonel Waterhouse essayed to repeat them, but did not succeed, and wrote to Liesegang to this effect. Liesegang again went through the experiment, and found that the phenomenon was due to the fact that he had been using an old solution. He also found that a fresh solution exercised the same effect if acidulated.

Mr. S. H. FRY asked whether it might be confidently assumed that the results after reduction by persulphate were not liable to change.

Mr. TRAPE, in reply to a question, said that the length of washing which was necessary after reduction depended upon the gelatine of which the emulsion was made, but half an hour was a fair average.

Mr. A. HADDON said that the proper procedure would be to wash well after immersion in the sulphite, and afterwards fix in a strong hyposulphite bath. The persulphate formed sulphate of silver during the process of reduction, and the washing water partly converted this to chloride. Obviously this should be removed, and therefore the plate should be treated with hyposulphite. If not done, the plate would be affected by light. Sulphite only stopped the action of the persulphate, and was not an energetic fixer. Sulphite, however, should not be dispensed with. If only hypo were used, there was likely to be a deposit of sulphur. It was important that after the sulphite the plate should be well washed and then treated with hypo.

Mr. EDWIN BANKS said he had seen negatives reduced with persulphate which in a few weeks darkened appreciably through the presence of free silver. As the last speaker remarked, they should have been fixed in hypo afterwards. No negative was safe without it. There was no loss of quality as a result of the fixation. The sulphate formed by the reducing salt was not very soluble, and, moreover, it is in close union with the gelatine, and not easy to remove.

### PHOTOGRAPHIC CLUB.

JULY 19.—Mr. F. A. Bridge in the chair.

Mr. E. W. FOXLEE referred to the exhibition, by Mr. Müller, of one of the impressions made by the electric inkless printing machine, which, after a fortnight, became a deep yellow-brown colour all over. Mr. Foxlee said he had an impression made at the same time, but printed on one side only, which he had left on the mantelpiece quite unprotected, but no visible change had taken place. He rather suspected that the change had been wrought by exhalations from the dye of the pocket or coat in which it had been kept.

Professor STEBBING, of Paris, passed round a number of photographs made at his studio. Theatrical beauties formed the subjects in most, if not all, the pictures shown, and the great diversity and freshness of their pose was very much admired. He said that albumenised paper was the printing method he employed, and that gelatine and collodio-chloride papers found little demand amongst Parisians. The question of copyright arose in connexion with a remark that one of his pictures had been reproduced, and it was stated by the Professor that in this matter of reproduction he found the German proprietors more honest than English publishers. There was a long discussion as to fighting cases of infringement, whether piratically or innocently done, and the help afforded by the Copyright Union to this end was especially mentioned. The point was also discussed as to whether, upon a case of unauthorised reproduction of an unregistered photograph, subsequent registration should be retrospective or not. Two or three spoke to the effect that the reproduction of certain photographs practically destroyed all chance of further sale, and the opinion was also expressed that publishers were sufficiently pressed as matters now stood, and several injunctions and penalties were named.

### Croydon Camera Club,—July 19.—

#### MY EXPERIENCES WITH KINEMATOGRAPHS

formed the subject of a chat given by Mr. MACLEAN at the above Club to a gathering of members which, considering the time of year, may be described as quite flattering. The lecturer prophesied the early and complete popularity

of this form of photography amongst amateurs, for not only was it comparatively inexpensive, but quite well within the power of any ordinary photographer. As regards the first point, he said a negative film which would show a picture of the usual length (about one minute) costs but the price of a dozen half-plates, whilst, as to ease and manipulation, Mr. Maclean handed round prints of his first attempt, which exhibited every indication of complete success. The construction and method of using various miniature cinematographs were next explained, the Birtac, which was highly commended by the lecturer for its reliability, being first shown. Next came the Biokam, which was described as a remarkable assemblage of ingenious ideas in a very compact form. This camera, which costs but six guineas, is not so large as an ordinary hand camera. The above were both shown in action, and their various merits compared. Each one was found to possess special advantages, which are the most important it must rest with the individual to decide. The procedure followed by the lecturer in winding the long celluloid ribbon on to a winder formed of cross metal rods studded with pins, and developing it by immersing the whole in a twelve-inch by ten-inch dish, was duly explained. A number of useful hints derived from practical experience with cinematographs were amongst the most interesting of the remarks, including, as they did, several laughable anecdotes of unrehearsed effects which were met with.

### FORTHCOMING EXHIBITIONS.

1899.

- August ..... One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C.
- Sept. 22-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- „ 25-Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18-24 ..... Croydon Camera Club.
- „ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

A. H. Pestel, 49, Terminus-road, Eastbourne.—Photograph of H.R.H. the Prince of Wales.

ADDRESS WANTED.—R. T. W. says: "Can you tell me the address of Barr, the lens-maker, as I want another flange for 15 x 12 lens."—The address is Wakefield-street, East Ham, London.

GLENDROCK.—Our reply was based on the assumption that Russia was a signatory to the Berne Convention. If she is not, then of course you have no remedy. Sorry if we have (unwittingly) misled you.

AGREEMENT.—EMPLOYER. Your queries involve two or three very knotty points, upon which we are unable to give an authoritative opinion. We should advise you to consult your solicitor on the matter. If you do, he will probably advise that counsel's opinion be taken on the subject, as several intricate points of law are involved.

POSITION OF STOPS.—HERTS. Some of the earliest portrait lenses by A. Ross were fitted with stops in front of the anterior lens, in the hood, so they were by most of the early makers; but the proper position is as they are now fitted, i.e., between the glasses. The instrument you have can be fitted with stops in that position with advantage, the cost would not be great.

LANTERN SLIDES.—C. WICKS. You are confusing two processes. What are known as glass positives are of no use for the lantern, as they would show on the screen as negatives. The term "diapositive" which is used on the Continent is a transparency made from a negative.

REPAIRING PORCELAIN DISH.—J. J. J. If the dish is broken in three pieces, we should say it would be a waste of time to try to repair it, so as to be used again for photographic purposes. The cost of a 12 x 10 dish is so small as to make the attempted repair not worth the trouble.

BRITISH MUSEUM.—H. CROFTS. Permission will have to be obtained before you will be allowed to photograph any object in the British Museum, or to take photographs of any of the rooms generally, and, in fact, to take a camera at all into the building. Make an application in writing to the Trustees, and it will, doubtless, be granted if your object is explained in the application.

SENSITISING PAPER.—P. McAVOY says: "In trying to sensitise some rough drawing-paper, after salting it with a fifty-grain solution of nitrate of silver, I find that the cotton-wool used discolours directly it is put into the solution, and, when the paper is coated, streaks show in the direction it is applied. Is it the fault of the silver?"—No; evidently the cotton-wool contains some deleterious matter.

REGISTRATION OR PATENT.—INVENTOR says: "I have invented a hand camera which I believe is an entire novelty, and I do not wish to go to the expense of patenting it. Could I not protect it by some sort of cheap registration like designs are registered?"—No; the only way of protecting an invention of the kind is by means of a patent. You may register a name for the apparatus, but that will not prevent any one else from making it.

BOOK ON WET COLLODION.—AJAX says: "Can you recommend me a handbook to the wet-collodion process? In the ALMANAC for 1896 is a most excellent paper on the subject, but it does not deal fully with small details. I have Captain Abney's *Instruction in Photography*, but I want a handbook devoted to wet collodion only."—In reply: The *Wet-collodion Process*, by Mr. C. W. Gamble, published (we believe) by Dawbarn & Ward, might suit your requirements.

BLACK TONES ON P.O.P.—WATERLOO says: "1. Will you kindly give me a formula for obtaining black tones on Ilford P.O.P. so that the prints will appear to be Velox or Gravura? I saw the following in a paper some time ago, but it will not act: Water, 16 ounces; powdered chalk, 100 grains; calcium chloride, 2 grains; gold chloride, 2 grains. 2. Are the operations different to ordinary toning?"—1. We know of no toning bath that will yield prints that will appear as if they were on either of the two papers mentioned. Why not use either of those papers? 2. Both Velox and Gravura are development papers.

INSURANCE.—J. W. It is very general for insurance companies to limit in the policy the value of the negatives to a certain sum as a maximum, usually a shilling. It does not follow, however, that they will pay the shilling each for all the negatives destroyed in the case of fire. It will have to be proved that they all are worth that sum, and many old-stock negatives are worthless. You say that you have "many negatives that are worth pounds each, and it would be hard to have to accept a shilling each for those in the event of accident." Quite so, but the fire insurance companies will insure the more valuable ones separately for any sum that may be agreed upon at an enhanced premium.

HALF-TONE FOR CONTACT PRINTING.—AJAX says: "1. When photographing an object which gives dense heavy shadows, impossible to avoid, would there be any advantage in using a ruled screen in front of the dry plate? I enclose a platinotype print to show my meaning. Would the use of a ruled screen break up the dense blackness of the seat on which the figure is seated, also the shadows on the face, and so enable me to get a better print on paper? I do not want to make zinc blocks from the negatives. 2. Verfasser's *Half-tone Process*, which you recommended to me last week, is an excellent guide. Can you tell me of a similar work on line-block making?"—1. We should say not. The fault in the enclosed picture is that the negative was much under-exposed and over-developed. Give more exposure, and soften the shadows by lighting them up by means of a reflector. 2. *Photo-zincography*, by Fritz, published by Dawbarn & Ward.

DISCOLOURED PRINTS.—G. & A. BARBER write: "Will you please answer my letter through your Answers to Correspondents column or per return post. I enclose print which has been toned and fixed along with about a hundred more. I sent the print (which had not been in alum) to a fresh firm for enamelling (collodion), and they wrote and told me that my prints, on being put through the preparations for enamelling, all changed colour. They sent me five or six back, and, as the lot they sent back didn't seem to have changed much, I wrote and told them to let me have finished prints home as soon as possible. They say the prints change colour through imperfect fixation, but the remainder of batch, toned and fixed same time, which I mounted and sent out (plain), did not change the slightest. 2. Will you let me know if putting them in alum after they have been fixed and washed will change them if they are not properly washed after alum? 3. Can you tell me the preparation they mention which has turned their colour. 4. As the photographs could not be sent out, and I have had others to start printing in their place, and if, as I think, they are to blame, did not they ought to allow me something for my delay, trouble, and expense? I enclose copy of their letter, which they kept counterfoiled, and should be glad either for reply per return or through your valuable paper."—1. The print you send bears unmistakable evidence of imperfect fixation. 2. Not if they are perfectly fixed and washed. 3. Probably a simple solution of gelatine. 4. No, as the fault does not rest with them,

## EX CATHEDRA.

IN the battle of the printing processes that is being continuously waged amongst photographers the carbon process occupies a unique place. It is rarely, if ever, subjected to attack on the score of any intrinsic disadvantages it may be supposed to possess. The scope for chemical or physical drawbacks or difficulties is narrowed down to the most confined compass when your printing process is one by which you form your image of finely divided carbon pigment in pure gelatine. Herein the physics and chemistry of photographic printing find their simplest expression. Practically speaking, beyond the insolubilising action of light on the bichromated gelatine no strictly chemical reaction takes place in the process, and "development," if it may be properly so called, introduces no complications whatever. Chemically regarded, carbon or pigment printing is the simplest of photographic printing processes.

UPON the æsthetic charm that always characterises a good carbon print it is not necessary for us now to dilate, nor need we dwell upon the many special purposes to which the process

may be adapted. But we have found ourselves reflecting that amid all the controversy that rages upon the merits and demerits of albumen, gelatine, collodion, bromide, or platinum, carbon printing appears to escape any serious amount of objection. The number of those who use the process is perhaps gradually on the increase, and we seldom, if ever, hear of a case of its being abandoned. There must be something peculiarly satisfying in a photographic printing process which after nearly forty years of existence still finds undiminished favour.

\* \* \*

ALMOST while we have the pen in hand, the Autotype Company, of 74, New Oxford-street, write us on the subject as follows: "There can be no doubt as to the increasing popularity of the carbon process, and, from our experience in supplying material and apparatus, we find that some amateurs hesitate as to taking up the process, believing that, in order to work successfully, a somewhat costly and complicated installation is necessary. This erroneous notion we have sought to remove, and we believe the introduction of this thoroughly practical set at a moderate price should prove a great boon to the amateur."

\* \* \*

THE set to which the Company refer consists of the following articles: Printing frame and pad, simplex actinometer, sensitive tissue (two dozen half-plate or four dozen quarter-plate), single-transfer paper (two dozen half-plate or four dozen quarter-plate), slate mounting slab, squeegee, blotting boards, two cold-water dishes, one developing tank, enamelled alum dish, box of powdered alum, book of instructions, *First Steps in Autotype Printing*; and the cost of the outfit is fifteen shillings. This set, which is excellent value, appeals to the amateur worker, who, never having tried carbon printing, would, we are sure, be delighted with the ease and simplicity of printing by "water development." We have much pleasure in giving publicity to the fact that the Autotype Company make special provision for amateurs desirous of taking up carbon printing.

\* \* \*

WE have received the Annual Report of the Council of the Röntgen Society for the year ending June 30, 1898. Mr. Wilson Noble is the President for the year 1899-1900, and the new

Hon. Sec. is Mr. F. H. Low, M.B., 12, Sinclair-gardens, West Kensington, W. A perusal of the report shows that much useful work has been accomplished by the Society in discussing the phenomena of radiography. The Society now numbers 148 ordinary and 5 honorary members, and the Council say that "fresh evidence is being continually received of the value of X rays in surgery, and the Council believes that there is much useful work open to the Society in the way of stimulating improvements and apparatus and in methods of investigation."

A BRIEF communication from Mr. Frederic E. Ives apprises us that his present address is 1324, Chestnut-street, Philadelphia, U.S.A. The kromskop system of colour photography is being prominently exploited in the States by Mr. Ives himself, and he tells us that very important improvements have recently been made in the instrument and that new patents have been obtained. The improved kromskops and appurtenances will be ready for sale on September 1.

MANY photographic firms will, doubtless, wish to have a resident representative in Paris during next year's great Exposition. We are asked by Professor Stebbing, the well-known photographer, of 30, Rue de Grammont, Boulevard des Italiens, Paris, to state that he will be in a position to accept agencies of this character, and will have the time to devote himself to the interests of photographic houses taking part in the Exposition. Professor Stebbing's long acquaintance with all branches of photography should qualify him to act to the best advantage in such a position.

THE *Journal* of the Royal Photographic Society states that, at a meeting of the committee of the Liverpool Section of the Society of Chemical Industry, held on March 16, 1898, it was decided to establish a memorial to the late Dr. Ferdinand Hurter, as a recognition of his work in applied chemistry and masterly investigations. The memorial is to take the form of a Hurter Memorial Lecture, associated with the Liverpool section of the Society, which will be given in alternate years on some subject connected with applied chemistry. In order to provide a suitable honorarium for the lecturer, a sum of at least 300*l.* is required, and the Hurter Memorial Committee have issued an appeal for help in raising the sum necessary for the endowment of the lecture. About 250*l.* have been subscribed, and the Hon. Secretary of the R.P.S. will be glad to receive further subscriptions to the fund from members of the R.P.S. who may wish to subscribe to a memorial of one who has done so much for the science and practice of modern photography.

MESSRS. R. & J. BECK, of 68, Cornhill, write us: "In an account in most of the daily papers of Mr. Percival Spencer's adventurous trip across the Channel in a balloon, by an error it was mentioned that he used a French camera. We should be glad if you would point out to your readers who may be interested in the matter that it was a 5 × 4 Frena camera that he used, carrying its forty films like a pack of cards." We have much pleasure in complying with Messrs. Beck's request. An account of Mr. Spencer's trip appears in another part of this week's *JOURNAL*.

THE English expedition to America to observe the total solar eclipse of May next will be in charge of the Rev. J. M. Bacon, whose work in connexion with the Indian Eclipse Expedition, and later in the way of balloon and wireless telegraphy experiments, is well known. Mr. Bacon will be accompanied by Mr. Nevil Maskelyne. It is considered that there will be a better chance in the United States of getting valuable observations of the May eclipse than in either Spain or Algiers, where stations will also be established.

A RECENT issue of the *Daily Mail* contained a humorous account of a curious adventure which lately befell a party of amateur photographers at Barmouth. They went out fishing and returned with an abnormal catch of bass, a circumstance which excited considerable comment and suspicion. The rest of the tale is best told in the *Daily Mail's* own words: "A day or two later the climax was reached. The three mysterious visitors went out for a sail, taking their cameras with them, and on their return they found 'Hawkshaw,' an elderly gentleman, waiting for them, who, immediately they stepped on shore, demanded to search the boat and tackle. Mr. Charles Bassano absolutely refused to allow him, whereupon 'Hawkshaw' produced a certificate, showing that he held the post of inspector or some similar office. 'Right you are,' said the trio, and forthwith they proceeded to get the cameras out of their cases. But the crafty Hawkshaw was not to be deceived—he must see the inside there and then of these boxes. Mr. Bassano to this retorted that, if 'Hawkshaw' dared to open the cameras, except in a dark room, he would sue him for damages. This resulted in the whole party—the Messrs. Bassano, 'Hawkshaw,' and a policeman—marching into a dark room. Mr. Fred Bassano's camera was opened first, and 'Hawkshaw' was at length convinced that it was a camera. The case, however, assumed a serious aspect when it came to an examination of Mr. Chas. Bassano's camera, for 'Hawkshaw' came upon a loose spiral spring which holds the films down. 'Ha!' he exclaimed, 'this is quite different! Now we have got something important.' It cost the photographer, to whom the dark room belonged, a lot of trouble to convince the old gentleman that this camera was not some lethal engine for killing fish. When he had accomplished this feat the photographer wanted payment for his time and the use of his room, 'Hawkshaw' at once declared that the Messrs. Bassano must do that, and in this exposition of the law he was backed up by the policeman. Now the talk of the group of fishermen on the quay turns on the big law case that may go to 'coorts in Lunnon' and which will settle the great question, 'Who pays the photographer?'"

It may be of interest to note that the little boxes which the inquisitive old gentleman appeared to regard either as receptacles for fish or as secretly worked machines for luring the inhabitants of the deep from their aqueous homes, were "Tella" cameras. Mr. Charles Bassano thus writes to the Company: "Yes, the cameras which caused the Barmouth adventures were Tellas, and you can make any use of that fact you like. Wasn't it funny? I am pleased with the working of mine, it has never failed once, and I have some good negatives. Better advertise that the Tella is good for photographing, but does not catch fish."

THE Tella Camera Company Limited, of 110, Shaftesbury-avenue, W.C., ask us to notify secretaries of photographic societies that they are ready to fill up dates for lectures and demonstrations on their Tella camera by Mr. W. E. Dunmore, a Director of the Company.

\* \* \*

THE prospectus of Secco Films (British and Colonial), Limited, has been issued. The capital is 100,000%, of which 66,667 are offered for subscription, 20,000 of the issue being appropriated to provide working capital, the balance of the nominal capital being allotted to the vendors in part payment of the purchase price. The directors are Sir R. T. Goldsworthy, Major Patton-Bethune, Mr. O. Treherne, Mr. T. C. Hepworth, and Mr. P. E. Butler.

\* \* \*

To the technical properties of Secco films we made full reference in our issue of July 7 last. Reproductions of negatives obtained on the film accompany the prospectus, and there are included the opinions of many eminent British and Continental photographers upon its capabilities. As we have over and over again pointed out, there is a large and growing demand for flexible films amongst amateur photographers and others, so that the Secco Company could hardly appear at a more appropriate time. At the press demonstration of the film a few weeks ago we subjected it to severe trial, and found it work with exceeding ease and facility. In this respect we are convinced that its chances of success are undeniable.

#### PHOTOGRAPHING MACHINERY.

THE needs of engineers and other manufacturers of photographs of their products have produced, in large towns where there is work enough for him, a specialist in this particular line—the “technical” or “engineers’” photographer; but in small manufacturing centres work of this description must naturally go to the local professional, or perhaps we ought to say that it would go to him if he could always be depended upon to turn out what the manufacturer wants. It is easy enough to set up the camera in front of an engine or machine and to get what the photographer himself may consider a satisfactory negative—an opinion which may not be shared by the customer when he gets the proof. It is wise to bear in mind that a photograph of this kind is a record pure and simple, for preservation by the firm or for despatch to customers as a guide to the merits of the machine; hence every effort should be made to render the photograph a full and accurate delineation of the subject, and we may therefore be excused for letting fall a few hints in regard to points in the work which may not perhaps suggest themselves to the portraitist.

Most machines in course of painting have a coat of “grey filling” given to them, prior to the application of the final colour and its subsequent varnish. If possible, arrangements should be made to take the photograph at this stage; the matt surface gives no trouble from reflection, whereas the finished machine often reproduces with a most objectionable lot of markings, due to reflection of surrounding objects from the varnished surface. If it is not practicable to make this arrangement, some improvement may be effected, provided the course is not objected to, by dabbing the bright painted

parts with putty. At any rate the bright steel parts should be painted with a mixture made by adding enough white lead to turpentine to make a thin cream, adding lampblack to deepen the colour as much as may be desired, and then adding one sixth its bulk of gold size to the mixture. This can be easily removed afterwards with a rag dipped in turpentine.

The lighting of machines in shops or engines in the open yard has generally to be made the best of by what means the photographer himself can devise, since it is rarely convenient to take the photograph anywhere but in one particular spot. The defect most frequently met with, both indoors and out, is too much top light, the result of which is to produce heavy shadows which obscure the details in these parts. It is therefore necessary to illuminate these shadows by artificial means. Reflecting screens—a white sheet, or, better, tinfoil attached to wood or cardboard—can be used. Sawdust, or white sand, strewn on the ground round the base of the machine, is by no means a bad substitute for these; or a line of flash powder, placed as close to the subject as is consistent with its exclusion from the field of the lens, can often be used with advantage. Any flash powder answers; we have found a home-made mixture of equal weights of magnesium powder and potassium permanganate quite satisfactory; care should be exercised, too, in placing the camera; a lower point of sight than usual frequently allows details to be seen which would otherwise be missed.

In the matter of backgrounds, an absolutely white background, if it can be so called, produced by painting round the machine on the negative with opaque pigment, is preferred by many. This entails a considerable labour when, as is often the case, small details, such as handles, steam cocks, project from the profile of the machine. Blocking out is done in the usual way, using a “duck” sable hair well charged with opaque colour. If electric light is available, an incandescent lamp placed beneath the negative is the *beau-idéal* of an illuminant for fine work of this kind; otherwise the usual reflector of the retouching desk or a mirror in its place.

It is well to avoid handling the film with greasy fingers before blocking out, for the blocking colour refuses to “take” easily to the parts affected in this way.

Sometimes the availability of a sheet or canvas, which can be rigged up on a temporary frame as a background, does away with the necessity of blocking out. Should this be defaced by dirt or holes, which is very likely to be the case if it is unearthed from somewhere on the premises for the use of the photographer, the reproduction of any markings in the negative can be prevented by enlisting the services of a couple of labourers to keep it gently moving during exposure.

Some object should be included to give an idea of the size of the machine—in the case of a large machine, a man, who, by the bye, should look at the machine, and not at the camera; in the case of a small, a six-foot rule, boldly graduated into feet.

Development, after ample exposure, is not difficult, and the photographer cannot go wrong in using, to commence, a developer made up as for portraiture, that is, weak in pyro. When all detail is out, a further quantity of pyro may be added to secure a vigorous image.

To those who have done work of this kind these few notes will, doubtless, appear superfluous, but to many photographers, whose work is confined pretty well to the studio, they will, it is hoped, prove helpful, and assist them to follow up a by-path of

business which allows a larger margin of profit than much of present-day portraiture.

We may add that, when the photographs are required for the illustration of catalogues, the photographer should, if possible, undertake the supply of the process blocks not only on the score of the profit on the transaction but that he may exercise some oversight in the matter of the photographs being well reproduced.

**Stereoscopic Illustrations.**—It has been stated so often during the last decade that stereoscopic photography was going to boom, though, so far, the results have not justified the prediction, that it is scarcely safe to prophesy; but at the same time we are bound to say that at the present time there is a strong under-current of feeling that at last the stereoscope is really going to have an innings. A straw is said to show which way the wind blows, and the latest wind indicator regarding this subject comes in a form which has great promise. Messrs. Pearson's, Ltd., have recently published *Impressions of America*, by T. C. Porter, M.A., F.C.S., &c., which is illustrated by diagrams and stereoscopic views. Referring to this work, *Nature* says: "The great merit and unique character of the work depends, however, not upon the author's impressions or his theories, but on the incomparable series of photographs which he took. These are reproduced in the form of stereoscopic views, and a neat little lenticular stereoscope is supplied with the volume. . . . They are reproduced by the half-tone process as separate plates, and very well printed." Now, it is quite evident that, if only a few more books were printed under similar conditions, the reintroduction of the stereoscope and its charming effects is simply a matter of time.

WITH regard to the use of process prints for the purpose, there will need to be great care exercised in obtaining clean blocks, and in making use of as fine a grain as possible. Without having made an actual trial, we should be inclined to predict that, with any but a very fine screen, the grain so familiar in process prints will become very offensive in the stereoscope, in a degree far in excess of the mere magnification induced by the use of a lens for viewing with. The effect in the stereoscope of the merging of the two prints in one is entirely marred if there be any unevenness of texture. This texture is not merely magnified, but, by a curious optical phenomenon, the irregularities present themselves to the eye apparently in different planes. This effect is seen in perhaps the most striking manner by the following experiment: Give a typesetter a small paragraph to set up twice over, spacing and justifying in as nearly similar a manner in each as he possibly can. Then let the two paragraphs be mounted stereoscopically, and view in the stereoscope. No matter how painstaking the compositor may have been, the letters will appear in the instrument at various levels, instead of coalescing and on to one plane, as might have been imagined would be the case.

**Ancient Inventions Revived.**—During the past week the daily papers have been describing, at some length, a system by which fountains at the Crystal Palace are to be illuminated next week. This consists of illuminating the water, as it leaves the jet, by a strong electric light; and elaborate descriptions are given as to how it will be done, &c. As a matter of fact, water illuminated in this way seems to absorb the light and carries it with it into the air. All the accounts we have seen of what is to be done have treated it as a new and novel idea. That is not so, however, for it is as old as the proverbial hills. As far back as the fifties, at the Panopticon of Science in Leicester-square—now the Alhambra—while under the management of Mr. F. H. Wenham, if we mistake not, the illuminated fountain was made a feature of for a long time. It was a single jet of water, of large size, illuminated at the jet by means of a powerful electric light, and projected up to the dome of the building; there it was still further illumined with another powerful

electric light. During the display, various colours were introduced at the source of light, and the thing proved a great attraction. Directly afterwards, the Royal Polytechnic Institution, then a place of scientific entertainment, followed suit with an "illuminated cascade" where, again, the water was illuminated at the point of its issue by the electric light. Verily, "there is nothing new under the sun" even in public entertainments.

**Purifying Acetylene.**—This is a subject of ever-present interest, for it is well known that the impurities accompanying the gas as disengaged from the carbide have often been the *finis et origo mali* in the accidents that have occurred in its use. Sulphuretted hydrogen is offensive, phosphoretted hydrogen is dangerous; both are liable to be present. According to some recent experiments by Herr P. Wolf the percentage proportion of these gases in the acetylene evolved from American and Swiss carbide respectively have been '02 and '04 in the former, and '02 and *nil* in the latter, while some carbide of the most recent manufacture is still purer. The sulphuretted hydrogen is diminished in quantity by having a large excess of water in the generator. Frank's method of purification consists in using acid solutions of certain salts, particularly chloride of copper. There is some waste of acetylene by a portion being converted into aldehyde. Herr Wolf proposes to use chloride of lime containing a small proportion of an alkaline chromate, the acetylene undergoing no absorption. Frank states that the solution he uses can be placed in an enamelled vessel, and that a single litre of it is capable of purifying fourteen cubic metres of acetylene, and that even this small amount of liquid need not be wasted, as it can be again utilised by boiling and subsequent aeration.

**Liquid Air.**—This wonderful agent is now an ordinary commercial product, and it is quite possible that its introduction may enable it to be applied in some branches of photography. A Mr. Brady, of Chicago, is stated to have designed and patented a cask in which liquid air may be stored. A company is at work in New York making the liquid, and the possible output appears to be very considerable. We read that, when the apparatus was in full work, the liquid air issued from the discharge pipe at a rate which indicated one gallon per minute as of easy production.

**Old Processes Rediscovered.**—A fortnight ago it will be remembered that we emphasised a suggestion, made in the *American Journal of Photography*, that it would be interesting, and perhaps useful, to experiment with some of the obsolete processes with the light of modern knowledge—a suggestion, by the way, that we have often thrown out before. In a translation of an article in the *Photographische Correspondenz*, by Professor E. Valenta, given in our last issue, on "Printing with Bichloride of Mercury and Citrate of Iron and Ammonia," the Professor treats paper with bichloride of mercury, ammonio-citrate of iron, and citric acid. The process, as given, is interesting, and it is very like an old friend in a new garb. If we turn to p. 57 of Hunt's *Manual*, fourth edition, published in 1854, we find a section devoted to the photographic properties of mercury, in which the writer says: "But, if the mercurial salt be subjected to the action of light in contact with the ammonio-citrate or tartrates of iron, the effect is far more powerful . . . is endowed with considerable sensibility, and darkens to a very deep brown, nay, to complete blackness, on a moderate exposure to a good sun." The method of Hunt was somewhat different in detail from that of Valenta. The former used the mercurial proto-nitrate, and the latter the bichloride. Hunt's difficulty was in the fixing the image. However, Valenta's process serves to confirm what we have frequently said before, that it will be well to unearth and overhaul some of the earlier and forgotten processes—unknown to the majority of modern photographers—with our present knowledge of photo-chemistry. Some of them have already been turned, with but little modification, to practical account.

**The Vandyk Tercentenary.**—English photographic tourists in Belgium will do well to bear in mind the Vandyk tercentenary, which will be inaugurated on the 15th inst. The opening of the Exhibition will be preceded by a street procession, as in the case of the Rubens celebration of 1877, in which, in the civic *cortège*, some of the most famous canvases of the great master will be displayed. Here will be novel food for the tourists' hand cameras. There is also to be a religious service in the famous Cathedral. The pictures, 106 in number, are drawn from all parts of Europe. Belgium, the country of Vandyk's birth, contributes thirty-one of his works, while England contributes thirty-seven. This is not altogether surprising, seeing that the great master spent the greater portion of his life, and did the greater part of his work, in this country. We learn that the collection, while on view, is insured for 400,000*l.* This seems a somewhat small sum when it is considered the large prices some of the great artist's work has realised here at times within the last few years, and that the Exhibition will include some of his best pictures. Be that as it may, snap-shots of a civic procession, with several famous pictures, to celebrate an artist's tercentenary, will form interesting food for the camera.

WHILE on the subject of picture exhibitions, it may be mentioned that, at the meeting of the Court of Common Council last week, it was decided that the Loan Exhibition at the Guildhall next year should be of representative works by living artists of the British school. There was some opposition on the part of the Library Committee to having any show at all next summer, on the ground that the time was too short to get together a representative exhibition, but this was overruled by the Council. Most people will be glad to hear it, as it would be a pity if these annual exhibitions of some of the best pictures in the country were made only bi-annual instead of annual.

**Ben Nevis Observatory to be Closed.**—This Observatory will have to be closed in October next unless funds are forthcoming to keep it open. Anent this subject a question was put in the House of Commons, one day last week, by Mr. Buchanan, as to whether the Government had declined the sanction of a grant of 1000*l.* to enable the Observatory, the only high level one in this country, to be carried on for a further period of two years. In reply, Mr. Hanbury said the facts were not quite as implied in the question. The Government make a grant to the Meteorological Council of 15,300*l.* a year. They have abstained from expressing any opinion what proportion of that grant should be assigned to the Ben Nevis Observatory, that being a question for the Meteorological Council. In reply to a further question as to whether the hon. gentleman, on behalf of the Government, could induce the Meteorological Council to give a sum for the support of the Observatory, Mr. Hanbury said that we have already tried to do this, and apparently they do not think they ought to give it. One would have thought that the Council could, out of the grant, have afforded to give the paltry sum of 500*l.* a year to keep the only high level Observatory we have going for a couple of years more, particularly if it would aid in more correct weather-forecasting. Even approximately correct weather forecasts would be a great value to agriculturists at certain seasons, and at all seasons to photographers. At present the daily forecasts, as issued from the Meteorological Office, are little better than a farce. They are fairly correct in settled weather, such as we have been having of late, when we can do our own forecasting. It is in an unsettled state of the weather that we want to know more.

#### IRREGULAR-GRAIN PROCESS BLOCKS.

WHILST quite open to be convinced of the advantages, if not the superiority, of irregular-grain screens compared with the ruled screen, I have not yet seen any results which would stimulate me to enthusiasm. I would certainly welcome an irregular-grain process, by screen or otherwise, which would give a result as satisfactory for all classes of subjects as the ruled screen; but, so far, all specimens I have seen are apparently picked subjects. If I were to select half a dozen photographs and send them to some firm working irregular grain, I should most likely have

them all returned as "unsuitable for the process." This sort of thing rather shakes one's faith in irregular grain, especially when one recalls the fact that nearly every notable experimenter in "process," from Fox Talbot downwards, has tried to reproduce photographic tones in irregular grain for letterpress relief blocks, and yet no process has survived the ordeal of commercial application.

Nevertheless, irregular grain is a fascinating subject, and I have been smitten several times with a desire to follow it up, and have given it a trial in several ways, with disappointing results. This may be my fault, but, when I find so many others equally disappointed, I am led to the conclusion that there must be something wrong in principle.

The conclusion I come to is that there is a very essential difference between using a ruled screen and an irregular-grained screen. The former builds up its own image, reproducing the picture in another form, viz., as a mosaic of dots. In a sense it is not a screen, because its function is not to hide some parts of the plate and let others be operated upon. Nor must we regard it as something which scores the sensitive plate across with a lot of ruled lines which slice up the image into little squares. The proper light in which we must look at the action of the ruled screen is to consider every opening of its network separately, each having its own function to perform of taking in—actually photographing—a tiny section of the picture. I do not mean to say that in the space of each single dot there is some detail or gradation of the picture, like the sections of children's block puzzles, which, when all properly fitted together, form the picture, but that each opening of the screen is influenced by the amount of light that reaches it and forms a dot which is the optical equivalent of the tone of the picture at the point corresponding to the position of this dot on the plate. If the tone is dark, it will be a small dot; if it is a middle tone, it will be a middling-sized dot; whilst, if it corresponds to a high light, it will be a big strong dot, the negative of a very fine dot in the subsequent half-tone block. Thus the picture is built up simply of three or four sizes of dots, which have individually no more analogy to the form of the picture than the bricks of a house wall or the tesserae of a mosaic pavement have to the complete architectural design. The photographic lens is the optical bricklayer or paviour, forming out of heterogeneous elements a homogeneous structure.

If my theory is correct, I can assume that, were I to take a photographic print and rule it with lines like squared paper, I could render upon it an approximation of the photograph by blackening in alternate squares to correspond to the tones, filling the squares full for shadows, making round dots just to fill the squares for half-tones, and just dotting the centre of the square for high lights. If I bleach away the photograph, leaving only the dots standing on white paper, there should be a fair representation of the photograph, the illusion being more perfect the further the print is held away from the eye. If examined with a bi-concave lens, otherwise known as a diminishing glass, to reduce the dots to the fineness of a half-tone, the photographic effect will be very realistic.

In the *Process Year Book* for 1898, I carried out the same idea in a much neater way by having three type characters cast to represent half-tone dots, and gave the printer a copy prepared in the way indicated above, and he set up the type characters so as to form a mosaic of the picture in squares of  $\frac{1}{16}$  inch. A proof was taken from the "forms" and reduced by photography until the squares were about  $\frac{1}{160}$  inch. The result was then exactly equivalent to a half-tone of the same size made from the original photograph with a 100-line screen.

It is thus obvious that the half-tone reproduction with the ruled screen is nothing more than a collocation of dots, and the finer and more varied these dots are in size the more perfect will be the original. With 12 dots to the linear inch the result is dreadfully crude, with 120 it becomes quite passable, with 1200 (assuming it was possible to get that number) the result would be equal to the most delicate photograph. Again, with only three sizes of dots the result is coarse, with six sizes it would be better, whilst with an infinite variety of sizes, ranging from the needle-point dot to the maximum of the screen spacing, the ideal effect would be obtained. This is the whole theory of tone-rendering in opaque ink. How the dots are formed of varying size is another theory which I need not, for my present purpose, enter into here.

Now mark how different is the action of an irregular-grain screen. It has to be placed quite close to the plate to be of any use, and its function is purely that of a screen in the exact sense of the word. It screens those portions of the plate under the grain points; that is to say, it abstracts a certain part of the picture, so that in the proof from the resulting block the eye has to imagine the rest. It may be urged that this is exactly what the proof from the half-tone block conveys, the eye in this case also having to "imagine the rest." But there is a distinct

difference. The ruled screen, as I have shown, builds up a picture, whilst the irregular-grain screen hides, or takes away, something from it, leaving still sufficient to give the eye the impression of the original.

It may be asked, How is it, if this hypothesis be correct, that a certain selective action takes place in making a negative through a grained screen? When the negative comes to be printed, there is certainly fine open grain in the high lights, and coarse, close-lying grain in the shadows. The explanation of this fact is that lateral spreading takes place around the grain in the high lights, and probably this is aided by irradiation within the film. Even if we deposit bituminous powder in a fine shower on the surface of the dry plate, so as to form a grain which sticks closely to the film, we still get this spreading action. The result is to give a sort of spongelike texture to the negative, and, when this negative is printed, the positive result consists of fine isolated dots. In the deepest shadows there is practically no action; there is no contrast between shadow and grain, and therefore the grain has no effect, the part around the grain remaining as transparent as the part under the grain. In the half-tones there is a medium action, the spongelike texture being practically of the same degree of fineness, or coarseness, as the grain, because there is little spreading. On the whole, I think I am justified in saying there is no selective action exercised by an irregular-grain screen, it is merely screening. The picture is robbed of much of its brilliancy, because the screen has taken away something from the fulness of the half-tones; it has added a grain to the high lights and so degraded them, whilst it has taken little or nothing from the shadows. The result must necessarily be a false rendering to the original.

The case is not at all the same in the half-tone process with ruled screens. It is true that we cover the high lights with dots, and that the half-tones are reduced in tone, but these two faults are, to some extent, compensated in the best work by "greying" the shadows, so that the key of the picture is lowered as a whole. The dot effect which covers the high lights is, moreover, not strongly in evidence. If the dots are uniform and very fine, they simulate whiteness very well, only reduced in luminosity. The irregular grain, however, gives a dirty, degraded effect to the high lights, besides causing a falling off in intensity. The irregular grain, for instance, always looks harsh and unpleasing on the face in a portrait.

This brings us to the consideration of the class of subjects which may suit irregular grain. Generally speaking, smooth-surfaced effects do not yield pleasing results in irregular grain. Flesh tones, light, smooth drapery, polished surfaces, delicate skies, smooth water, detail with sharp outlines, are all unsuitable subjects, and are, in fact, just what one would expect to be unlikely for the purpose. Rugged or thickly foliaged landscapes, portraits of rough-bearded men, photographs of rough-haired animals, crayon or pencil drawings, are much more manageable subjects.

If, then, we are to select only such subjects as are suitable for irregular grain, it is hardly likely that it can ever be useful to such a widespread extent as half-tone with ruled screens. No half-tone man would think of refusing a copy as unsuitable; he will in all cases endeavour to make the best of it, and, as a result, we see the process used for every conceivable class of subjects. It is a universal process of reproduction, copying faithfully works of art, portraits, landscapes, seascapes, commercial objects, drawings, and, in fact, everything that can come within the range of the camera. And what is there to-day which will not yield an image to this all-pervading instrument, which sweeps the heavens, probes the depths of the waters, reveals the cavernous workings of man or nature under the earth, catches images of bullets and projectiles surging through the air, shows us birds when swiftly winging their flight, or calmly reposing in some inaccessible eyrie; everywhere, in fact, reading for us, or helping us to read, the riddles which a sphinx-like nature sets us poor mortals to worry our brains with?

The camera and the half-tone process seem more than ever destined to go hand in hand, the one taking the pictures, the other reproducing them, and, by the aid of the printing press, disseminating the same for the instruction or amusement of the million. The kindred processes of photography and photo-engraving have fulfilled a want of the age, and to that fact is owing their wonderful progress. The half-tone process has especially got a strong hold on the picture-loving public. The majority may not know exactly what it is, but they recognise that it is a method by which they get faithful representations of men and things. They have become used to the "screeny effect," which, indeed, is now so subdued in the best blocks that it passes unnoticed.

Now, is "irregular grain" going to have the same success, the same

widespread application? Is it going to be as universally pleasing to the public? I think not. It may please a few enthusiasts, but, after all, the great thing nowadays is to please the crowd if you would be successful from a pecuniary point of view.

WILLIAM GAMBLE.

## FOREIGN NEWS AND NOTES.

**Woven Photographs.**—In Dr. Liesegang's paper, *Der Amateur Photograph*, we read that one of the wonders of the approaching Paris Exhibition will be an automatic machine for taking photographs and reproducing them in woven material. The person wishing to be photographed will stand in front of a machine, place a coin in the slot, and pose until a signal from a bell indicates that the photograph has been taken. In fifteen minutes from that time the machine will deliver to the sitter a pocket-handkerchief with his photograph woven in the fabric. The process by which this result is obtained is only partially known at present, but it seems that the photographic image is formed of dots, and used for the production of a perforated image on a metal band. By means of these perforations the warp is raised in the loom and the wool forms a dot in the fabric. The assemblage of dots, by their relative position, forms the image. The wonderful part of the process is the rapid transformation of the dots forming the photograph into perforations upon a metal band, and, if this has been successfully accomplished, it constitutes an advance that may have considerable influence upon textile manufactures.

**The Latent Image.**—Dr. V. Schumann communicates to the *Archiv für Wissenschaftliche Photographie* a very interesting fact which he has observed. If a glass plate is coated with a very thin film of gelatino-bromide of silver, this covering will withstand the action of the strongest acids. Such a plate may be immersed in nitric acid (40°B), either before development or after fixation, without injury to the film, and neither the capacity for development nor entire destruction of the image takes place. These facts should prove that the latent image does not consist of metallic silver, and that the image after fixing is but partially formed of silver. It has been stated that an emulsion of AgBr, in contact with pure metallic silver, may be reduced to silver by development. Dr. Schumann has not found this to be the case with the ultra-violet plates which he prepares. If any reduction occurs, it is due to friction, pressure, or other mechanical means. He has not made similar experiments with ordinary plates, but has been assured, by those who have, that simple contact is insufficient to bring about reduction by a developing solution.

**Ammonium Persulphate and Halation.**—Dr. Meydenbauer mentioned, at one of the Berlin photographic societies, that he was induced, by the highly favourable reports concerning this reducer, to try the effect of it upon some old negatives of interiors, which he had found too bad to print, on account of the halation surrounding the windows. The result was highly satisfactory, the density of the windows being sufficiently reduced to permit of good prints, showing full detail in the windows, being made. A two per cent. solution, slightly acidified with sulphuric acid, appears to have been used.

**Testing Coloured Screens.**—Following the lines suggested by M. A. Villain, in the *Moniteur de la Photographie*, a contributor to the *Photographische Chronik* describes the following simple method for extemporising a colourimeter. Remove the lens from the camera, and for the focussing screen substitute a small board of suitable thickness. Cut two round or square holes, side by side, in the board, behind which two glass tubes of identical diameter and thickness should be affixed by wire or other suitable means. 15 mm. diameter and 15 cm. length are convenient dimensions for the tubes. If samples of the two solutions to be compared are poured into the tubes, very slight differences in colour may be detected upon looking at them through the lens flange. If necessary, light may be reflected upon the tubes by a looking-glass placed at a suitable angle. It is desirable to exclude all extraneous light by using a focussing cloth.

**Hand-camera Lens Adjustment.**—A patent has been granted in Germany to A. Theopold for a means of adjusting the elevation of the lens. A plumb indicator is affixed to the side of

the camera with a scale showing the angle of elevation or declination. A corresponding scale is marked on the rising front of the camera. The object to be photographed is centered on the finder, the angle read off on the scale of the plumb indicator, and the lens raised or depressed to the corresponding point on the scale of the rising front. The photograph should then be taken with the camera held level.

**Gum-bichromate Portraiture.**—The *Deutsche Photographen Zeitung* contains a very interesting letter from a Vienna correspondent, in which the method is described by which Herr Otto Schmidt, a professional photographer, has produced some very fine life-size portraits. The Vienna Photographic Association has recently awarded him the silver medal for the excellence of his work in this direction. Herr Schmidt, before turning to photography as a profession, was a water-colour artist of repute, and, doubtless, this accounts for the success he has achieved with that most plastic of photographic processes, the gum-bichromate. His pictures are the result of two, three, or four printings from the same negative. Landscapes are, of course, less difficult than portraits. Whatman's Imperial drawing-paper is sized with gelatine and chrome alum and covered with a very thin coat of gum-bichromate containing very little pigment. A soft negative is used and the highest lights are protected. The first printing gives an image very delicate in the half-tones. For the second printing rather more colour is used, and a harder result is aimed at by various means, such as the use of a screen of green glass, &c. The third printing is still harder in character, and in this manner the print is gradually built up from the most delicate half-tones to the deepest shadows. It will be readily understood that, by successive printings with pigments of suitable shade and intensity, the gum-bichromate process may be made to yield pictures with a great range of tone. In the hands of a competent artist the process should be capable of yielding portraits of exceptional merit.

## FLORAL PHOTOGRAPHY.

### II.

Next in importance to the providing of a suitable background comes that of, at least, some knowledge of how best to dress and stage many of the subjects that make excellent studies in floral photography. The dressing of, say, such a subject as a pot plant, so as to render it in the most suitable condition for being photographed, is an operation which too seldom receives attention by those who do not possess some knowledge of horticulture. By dressing is meant the alteration of the shape or contour of the foliage, as well as in some instances the pruning of certain portions that detract from the shape, and which produce eyesores in a greater or less degree; also that of not infrequently going so far as to add even additional blooms by cutting them from an entirely different plant of an exactly same species, and adding those cut blooms, in an extremely natural form, to any portion of the plant where the blooms are deficient. This treatment is largely practised by professional gardeners, and, as I write, I can recall a notable case that came under my observation some time ago, when I was commissioned to execute a number of photographs for the Curator of one of our large botanical gardens. The plant in question was considered a rare specimen of its kind; but the blooms, although exceedingly fine, were not distributed as equally over the plant as the Curator desired; so, on my proceeding to unlimber the photographic apparatus, a slight consultation was held among the gardeners, the result of which was soon seen in the production of another specimen of the same plant, and, having selected the best blooms on them, they were removed together with the entire branch bearing them, and a few minutes saw the plant that I was to photograph bearing these borrowed plumes, which any one outside the ken could never have detected as not belonging to the plant as depicted. I remember this mode of dressing a plant was a revelation to me at the time, but I have since learned that among professional gardeners it is quite a common proceeding where plants have reached a certain stage and it is desired to photograph as well as at times to exhibit them.

Any one whose horticultural experience is not great should endeavour to be present at the preparations of blooms and plants about to be displayed at a flower show. Here may be seen the professional dresser in all his glory, with ivory blade, knife, and tweezers, and certainly the watching of an expert dresser is a lesson to any one intending to photograph floral studies, which must prove highly instructive. Mark, for instance, the delicacy of touch with which he will handle, say, a number of prize blooms of exhibition roses; here the outer petals will be most beautifully curled and opened backwards by means of an ivory-bladed knife, and a few seconds of time will suffice to work quite a complete transformation in the appearance of the delightful flowers he has manipulated; and, the most marvellous thing of all, without injuring the

natural peachlike bloom of the petals. This preparation of blooms for the purpose of exhibition amounts to a fine art, if not, indeed, bordering upon the display of genius, and tends, in a marked degree, to the production of good photographic studies, simply by reason that plants are displayed with their blossoms equally distributed, even although many of them are, in point of fact, not borne by the plant itself, and but very few cases will be found where a plant in itself is not improved in appearance by such treatment. If the dressing of such subjects as pot plants becomes a question of importance, so does that of staging, especially from a photographic point of view, and in the staging operation we have a field which covers a very wide area, for almost every bloom requires a different treatment. Take, for instance, the staging of a spray of violas—without doubt one of the most charming exhibits to be met with in our autumn shows, and which lend themselves especially to photography. Every one knows that violas are more or less a delicate species of bloom, and unless they be very carefully handled and protected, their beauty will soon disappear; yet these fragile blossoms, when carefully staged, may be made to retain their almost pristine beauty for two or three days. A clever dresser well knows how to retain, not only the freshness of the blooms, but likewise how to maintain their shape for almost an indefinite period. In his treatment, he will very probably bring to his aid damp moss, knitting cotton, and very fine wire, and when to the blossoms is added the foliage of the violas, and they are relieved on a background of black or other suitable coloured velvet, the effect is charming.

From a photographic point of view much will depend on the selection of the most suitable varieties, especially in regard to colour, and the placing of these sprays of blossom in at least a somewhat natural position.

One of the best pictures of violas I ever witnessed was obtained by staging the sprays on a sheet of glass behind which was the velvet that was used as a background, at a distance sufficient to throw the pile out of focus; and the sprays were made to occupy a position so that the camera was pointed somewhat downwards when the plate was exposed. By making provision whereby an intermediate transparent screen of glass is caused to hold a subject *in situ*, so that a background is made to appear a fair distance behind, a delightful feeling of space is introduced, and the blooms do not give the appearance of being pasted or stuck upon the background like a postage stamp to an envelope.

In a previous article reference was made to the necessity of providing facilities for using the camera in a somewhat vertical position. A very little consideration will be needed for any one to understand that, as nearly every flower differs in form, some being somewhat rounded like the African marigold and dahlia whose crowns may be said to be their glory, others, on the contrary, are found assuming a somewhat flat surface with a drooping tendency, such as the single dahlia and pansy, and, were any one to attempt to photograph each of these subjects under exactly similar conditions of lighting and posing, the result would not be satisfactory, for in the one case the side only of the bloom would be depicted and a very false rendering of form be given; therefore hardly any two subjects will be found to suit the same method of lighting and posing.

In lighting we have a very important factor in the work we are considering, and, although much may be done in close proximity to an ordinary window, there is no doubt that the great bulk of subjects will be found best treated in the open air or in such a retired place outside as where a plant is capable of being lighted with a somewhat strong side and top direction of main light, a position often found in close proximity to a gable or high wall where one side of the light is shielded.

If the work is attempted indoors other than in studios, especial attention must be given to reflectors, and it is a mistake to suppose that white reflectors are the best to employ, for experience has shown the writer that, in dealing with coloured objects such as flowers, coloured reflectors are by far the best; but these will be found to depend very much upon the colour of the object being photographed, and any one having no experience of this work and who employs, say, a strong white reflector may even be surprised to find that on some subjects quite an effect of cross lighting will be produced by using it, whereas the employment of a pink reflector on subjects of a white colour yields a delightful softness and transparency in the shadow, far in advance of the results achieved by using the universal white fabric.

In this work a beginner will not be long in finding out that long-extension cameras are a necessity if anything like size of objects is desired, and long-focus lenses are a *sine-quâ-non*. Working at close quarters with them means heavy stopping down, and very long exposures frequently have to be given. In my belief there is no fixed rule to follow as to the employment of any special plate. Isochromatic plates and screens will be frequently required, but ordinary bromide plates are by no means outclassed by the former. So much will be found to depend upon the lighting and the colour of the object, as well as the requirements for which the object is being photographed; if, for example, half-tone blocks are to be made from the photograph, it by no means follows that isochromatic plates and coloured screens are the best to use, for in such work as book illustrations ordinary bromide plates will frequently yield a far better range of values which by the touching up by hand invariably produce better pictures for being photographed through a grating.

Some studies such as are in nature viewed by looking down upon, as in

the case of ferns, are best photographed in some position where a natural background can be used, and many delightful hedge-row studies have been acquired just as they appear in nature, but these are very difficult to obtain by reason of movements from the slightest breath of wind.

It must not, however, be supposed that with the production of a good negative this work is completed, for, no matter how good a negative may have been obtained, much may be done to improve the printing values of same by after-manipulation.

This may mean the strengthening of high lights and the reductions of same where they are too intense, in fact there is almost no limit to the working up of negatives of this class in which the application of transparent oil pigments in addition to the ordinary use of the lead pencil will be found almost invaluable. One thing, however, is certain, that in floral photography a very pleasant branch of work is open to all who care to expend a little extra cost in apparatus and take a delight in contemplating the wonders of nature as displayed even in an ordinary flower garden, and once a beginning is made it is almost certain that the worker will find himself imperceptibly being drawn into a closer union with matters horticultural from which he will be able to dive down into almost unfathomable depths of nature's wonderful creation. T. N. ARMSTRONG.

## ON THE ACTION OF LIGHT ON THE SALTS OF COBALT.\*

### EXPERIMENTS WITH COBALDIC BENZOATE.

COBALDIC hydrate is practically insoluble in a boiling aqueous solution of benzoic acid. For photographic purposes it is therefore necessary to prepare this salt by double decomposition. For the present series of experiments it was formed by resensitising paper, previously coated with cobaltic oxalate and dried with a strong aqueous solution of potassium benzoate. A mixed bath of these reagents, it should be noted, is not, as might be supposed, available for these operations, from the circumstance that cobaltic benzoate, unlike the great majority of the salts of cobaltic oxide, is insoluble in water. The salt resembles the formate in its behaviour under the rays of the spectrum, but is somewhat more sensitive to light. A sheet of the prepared paper was exposed under a negative to diffused daylight. In the course of eighty hours a faint brown positive image was obtained. Another piece was exposed to the action of the spectrum for seventy hours. The image obtained is represented graphically in fig. 14. The red rays and the orange are equal in intensity, whilst the yellow and the green exercise a weaker influence, and the remaining rays are apparently without effect. On immersing the print in the ferricyanide developing bath the above image was gradually destroyed, nor was any new image formed by development. In both experiments during the exposure of the paper to light it was found to absorb moisture.

By the action of hydrochloric acid upon a mixture of benzoic acid and cobaltic hydrate, an emerald-green solution is obtained, paper coated with which, and dried, is about twice as sensitive to light as the simple benzoate.

The constitution of this green salt has not been accurately determined, but it would seem probable that a part at least of the benzoic acid is converted into chloro-benzoic acid, which, in turn, dissolves the hydrate, producing cobaltic chloro-benzoate. To prepare this solution, benzoic acid and cobaltic hydrate are boiled together for a few minutes in the presence of water; the bulk of the latter is then decanted off, together with the lighter portion of the insoluble matter, and a little strong hydro-

FIG. 14.—COBALDIC BENZOATE.

FIG. 15.—COBALDIC CHLOROBENZOATE (?).

chloric acid is added, when the residue will readily dissolve, the application of a gentle heat facilitating the operations.

An exposure of fully forty hours in diffused daylight is necessary in order to produce an image by "printing out" on paper sensitised with

the compound in question. The deposit so formed is of a brownish-yellow hue, with a shade of green in the high lights.

Under the spectroscopic, an exposure of forty hours' duration produced a distinct impression on the prepared paper, due to the less refrangible rays, and represented in approximate outline by the dotted curve in fig. 15. The resemblance to fig. 14 is very evident, the intensity due to the action of the red rays being, however, a little more marked. The print was transferred from the printing slide to the ferricyanide bath, whereupon the impression was speedily destroyed, a new image taking its place. This is represented graphically by the overlapping curve in fig. 15. The rays operative in the production of this second image are, it will be noticed, precisely those which failed to exercise an influence in the formation of image number one. The effect is attributable mainly to the blue, the indigo, and the violet rays, the maximum point lying in the first-named. The green rays exercise a comparatively weak action, equal, however, to the average intensity obtained in the initial stage. To practical photographers, silver printers in particular, this experiment may serve to throw some little light on causes as yet imperfectly understood relating to matters of printing and development, showing as it does that, under certain conditions, the latent or developable image is attributable to rays of quite a different order of refrangibility from those which are called into play in building up the direct or visible image.

### EXPERIMENTS WITH COBALDIC URATE.

This salt may be prepared by dissolving cobaltic hydrate in a hot saturated aqueous solution of uric acid. The presence of a small quantity of ammonium urate facilitates solution, a fact which is probably to be explained on the supposition that a double salt is produced. Paper was coated with the ammonio-cobaltic urate prepared as above, dried, and exposed to diffused daylight beneath a negative. In the course of about ninety hours a positive image of a pale brick-red colour was produced. A second sheet was exposed to sunlight in the spectrum slide for ninety hours. The resulting image was similar in hue to the first, and, though of no great vigour, yet served to exhibit faithfully the extent and character of the spectral action.

A glance at fig. 16, representing the spectrum band in question, shows that the urate is sensitive mainly to the blue rays, these producing the maximum effect. The indigo rays possess a medium degree of power,

FIG. 16.—COBALDIC URATE.

the yellow an almost equal degree, the violet and the red a slight degree, and the green none whatever. The print, it should be added, failed to show any signs of a new image when soaked in the ferricyanide developer—in this respect resembling the benzoate.

### EXPERIMENTS WITH COBALDIC SILICATE.

For experimental purposes paper was sensitised with cobaltic oxalate, dried, and resensitised with a moderately strong solution of sodium silicate. The dried paper was found defective in keeping qualities, greyish patches and markings appearing on the surface in the course of a few days after its preparation. From the circumstance that a precipitate in all respects similar is formed when sodium silicate is added to the solution of a cobaltous salt, it is evident that the sensitising compound is gradually reduced to the cobaltous state without access of light. The presence of an excess of sodium silicate helps to delay this decomposition, but does not entirely arrest it. Instability of this kind is characteristic of a number of the cobaltic salts of the inorganic acids, though it is far from being either so common or so marked as some chemists have been led to suppose.

The cobaltic salts of the organic acids, on the contrary, are fairly stable bodies, and, except in those circumstances in which the conditions of experiment necessitate their exposure to light, seem to undergo but little change.

This paper was found to give a faint greenish-grey image under a negative in dull diffused daylight, thirty-five hours' printing being required. Under the spectrum an exposure of like duration produced a single faint band situated in the region of the indigo rays. When treated with the ferricyanide developer, no change ensued which could with certainty be attributed to luminiferous latent action. A second and a third strip of sensitised paper were successively exposed in the spectrum slide, the exposures given being respectively 95 and 110 hours in weak sunshine.

In neither case was there any appearance of the band in the indigo; but in place thereof a distinct broad band was produced in both under the yellow rays. Traces of a greenish-yellow deposit extending from the band towards the red end of the spectrum were observed in the first print.

\* Concluded from page 476, vol. xlv.

These, however, were absent in the second, having, no doubt, been destroyed by bleaching. The band in the yellow was also fainter, and, whereas formerly it possessed a greenish-yellow colour, now appeared of a pure yellow. Ferricyanide of potassium was found incapable of producing any alteration in the appearance of these prints beyond a gradual obliteration of the image already formed.

#### EXPERIMENTS WITH COBALTIC ALUMINATE.

A solution of potassium aluminate (prepared by adding gelatinous aluminium hydrate to a solution of caustic potash) was mixed in the proper proportions with one of cobaltic oxalate, and applied to paper by coating. A strip of this paper, after drying, was exposed in the spectrum slide for thirty hours, and gave a distinct but very faint yellow band under the red rays. A supplementary exposure of ten hours occasioned no change, nor did the application of the ferricyanide developer produce any extension of the image.

Another portion of the prepared paper was exposed for upwards of 100 hours in the slide, and examined at intervals. The yellow colouration was found to extend gradually in the direction of the green rays, and, having reached a little beyond the line *E*, it became stationary. At a certain stage of the exposure a bleaching action was set up. This increased hourly, so that at the close of the exposure the deposit was so faint as to be almost imperceptible.

An unsuccessful attempt was made to revive the image by development in a weak solution of argentic nitrate.

Whatever may be the exact nature of the decomposition effected by light in the case of the aluminate, it would at least seem, in the instances cited, that the salt was not reduced to cobaltous aluminate, otherwise a greyish-blue image ought to have been produced.

#### EXPERIMENTS WITH COBALTIC SULPHITE.

Paper was sensitised with mixed solutions of cobaltic citrate and sodium sulphite, a slight excess of the latter being present. After drying in darkness, a portion thereof was exposed to the action of the spectrum. No visible image having been impressed, the print was transferred to the ferricyanide bath. An excessively faint image of a purple hue was gradually deposited. The range of intensities could not be even approximately determined. Another strip, however, exposed for four hours in the same manner, failed to give any image when correspondingly treated.

A third and a fourth strip were successively exposed as before, but for a period of thirty hours each. One was then developed in the ferricyanide bath, and the other in an aqueous solution of mercurous nitrate. Neither exhibited the least appearance of an image. The addition of a few drops of dilute acetic acid to the ferricyanide bath occasioned no change that could be detected. A fifth strip, however, on being exposed to the action of the spectrum for sixty hours, though giving no image by "printing out," yielded a faint one when immersed in the ferricyanide developer. Fig. 17, representing the range of intensities obtained, will

FIG. 17.—COBALTIC SULPHITE.

be found to present several interesting features. The rays of a low order of refrangibility, to which so many of the cobaltic salts are sensitive, are here shown to be inoperative with the exception of the yellow rays, which, however, exercise only a weak influence. From the *D* line there is a gradual increase in the activity of the radiations extending to the region of the violet, the point of maximum intensity being apparently situated in the vicinity of the end of the visible spectrum. These experiments tend to show that cobaltic sulphite is but little sensitive to light. Like the silicate, this salt is liable to undergo decomposition in darkness when the paper is kept too long. In a week's time discolouration occurs at the margins, and in the course of a couple of months the originally white surface assumes a uniform yellowish-pink hue.

#### COLOURING PHOTOGRAPHS.

M. CHARLES DICKER, of Brussels, the inventor of this process, points out that the methods hitherto known for preparing coloured photographs indirectly, that is, not in immediate connexion with the photographic process itself, comply very imperfectly with the requirements which in general apply to the details of a photographic picture. The methods, moreover, in effect depend mostly upon the skill of the person treating the picture, and consequently the pastels, water colours, and oil paintings so produced are essentially nothing but pictures in which the more or

less skilled hand of the artist reproduces the details of the photographic pictures in various degrees of perfection. It is true that by an ingenious combination of covering and glazing colours an improvement has been effected, inasmuch as the transparency of the latter enables the fine lights of the photographic picture to be more clearly recognised; on the other hand, these transparent colours have absolutely no effect on the half-tones and deeper shades of the picture, so that for the colouring for the latter only body colours can be employed. Experiments have shown that it is best for the elegance and good effect of the coloured photograph if only such colours be taken which, so to say, themselves penetrate in the separate pores of the picture, and possess both a great intensity and also the quality of being easily absorbed. The aniline colours possess these qualities, but the application thereof is limited, apart from the drawback that the colours also can only penetrate in the photograph to a certain degree of saturation, which does not suffice to colour the deepest shades. In the case of photographs especially which are taken upon albumen or Aristo paper, this especially applies, whilst collodion or celloidine papers only possess the quality of absorbing the colours in the moist condition. From this come very many practical difficulties; for instance, the colours once laid on can no longer be removed, and the pictures, if spoiled, lose their value; moreover, the latter-named papers cannot be wetted as often as desired in order to retain their property of absorption, but, if they have once become dry, they have lost their quality for ever, consequently the colouring can only take place immediately after the removal of the picture from the last water bath, and the work, in view of the damp condition of the paper and the tendency of the colours to run together, makes a good effect almost impossible. Added to this difficulty for treating photographs in the unmounted condition with colour, there is another drawback, namely, that the deeper shades cannot take up as much colour as will effectively suffice for them, so that the drawbacks of the present system are sufficiently obvious. On this account the operation has been somewhat changed, and the photographs have been treated with concentrated solutions of aniline at the back, which colour is intended to penetrate through the picture and appear on front; but this method gives such a weak, uncertain colouring that, even when the photographs are made transparent, no sufficient effect is obtained; moreover, the sensitiveness of aniline colours to light renders a treatment of this kind almost worthless.

The present invention has for its object a process which possesses great simplicity in comparison with the methods at present in use, and also shows such extremely satisfactory results as to distance any other methods and be applicable by any one without knowledge of painting and without any particular skill. This method is characterised by the treating of the finished mounted picture with a slight covering of a gelatinous material, and then subjecting it at the requisite parts to the action of an aniline colour. By this device is attained that the gelatinous layer takes up the colour readily, so that the pictures possess such a brilliance and light that even the deepest shades appear to be thoroughly saturated with colour and produce a very great effect. Of course, in the carrying out of this process, certain practical points must not be neglected, and, even when by the new process the colours are caused to penetrate into the deeper shades of the photograph, it is desirable in taking these that only plates sensitive to colour should be used, so that certain special colours, such as red, yellow, green, and blue, which in the use of ordinary dry plates give false colour values, shall, in correspondence with the transparent colours to be used, possess a greater or less covering in the negative and positive copies. It is well known that certain colours, such as red, yellow, and green, are reproduced in photographic pictures even darker than they are seen with the eye, whereas, even when the ordinary orthochromatic dry plates which are supplied by the trade to some extent remedy the above-mentioned contrast, yet the negatives and copies thereof produced by these plates with transparent colours do not give such clear and correct coloured tones as is desirable for this purpose; even the interposition of yellow glass, when colour-sensitive plates are being used, does not create the requisite balance, and experiments have shown that the photographing takes place best with the aid of red sensitised dry plates and a green light screen. In order, moreover, to obtain a satisfactory result in the colouring of the photographic representations, it is necessary that the same (three ground colours which are hitherto made use of) shall be employed in the taking, partly as screens, partly as sensitisers, so that when, for instance, for the colouring of the positive prints red, blue, and yellow are to be taken, also, at the taking, the bromide of silver dry plate shall be rendered sensitive to colour by means of a red colouring material, whilst the blue and yellow colour solution serves for covering gelatine mirror plates, which, after drying, are used together as a green light screen. The highest lights in the copies must be pure white. Moreover, in copying, certain points of view must be kept in view; and, firstly, care must be taken that the prints receive a neutral tone as possible in the gold bath, so that, on the further treatment thereof with the aniline colours, no false colour effects are produced. The gelatinous covering, which, in consequence of its porosity, absorbs the colouring matter, is preferably prepared by means of white gelatine dissolved in water, because this article possesses especial advantage that it can easily be removed again by warm water in case the colouring has over-passed the edges, and so on.

In order to protect the aniline colours applied against the influence of

light, the gelatine is added to the salts of chrome mordants and so on; obviously other similar materials might be used instead of gelatine, such as collodion, glue, albumen, isinglass, starch, and so forth—in short, any gelatinous substance. In the colouring, care should be taken that the absorption of the colouring matter takes place at the same moment in which the brush comes in contact with the gelatinous layer. As, however, it is not possible to outline the parts of the pictures so quickly with the brush, and the absorption does not take place equally if the operation is slow, it is requisite, in order to prevent an unequal absorption from being visible, to apply the colours considerably diluted, and to repeat the operation several times, which, of course, prolongs the process.

In order to remedy this drawback, those portions of the gelatinous layer which are not to be coloured can be covered at those parts which adjoin the portions which are to be coloured with a spirit varnish insoluble in water. This is allowed to dry, and the surface to be coloured can then easily be treated with the colouring matter. Those parts to which the spirit varnish has been applied will absorb no colour, and can afterwards be easily cleaned, and the varnish removed by means of cotton soaked in alcohol. By the consecutive application of the three ground colours, the required shade can easily be attained. After the colouring is finished, the picture is coated with collodion, so that it is protected on the one hand against outside influences, and on the other hand the colouring is caused to appear more bright. The process is, of course, applicable with any kind of photographs, whether the same be upon paper, glass, porcelain, ivory, metal, mother-of-pearl, or other materials. In the case of production on a large scale, the three colours could be applied by means of printing or stencils.

#### PHOTOGRAPHY WITHOUT LIGHT.

"DR. W. J. RUSSEL has lately discovered that certain substances exposed in the dark room for several days act upon the photographic plate. That tin is one of these is certain" says Dr. Victor Schumann in the *Photographic Times*. "I proved two years ago its influence on dry gelatino-bromide emulsion. I have also recently repeated Mr. Russel's experiments as far as they refer to tin and gelatine dry plates.

"I applied the tinfoil sheets (which are sometimes manufactured of the thin commercial article, and sometimes of thicker material) in several ways. Some of the sheets were exposed at least eight days in the dark; some I exposed to the daylight, and others to sunlight. Before the application each sheet was polished with soft leather and Paris red upon a layer of plate glass, then laid in dark-room light on gelatine dry plates, and exposed from one to thirteen hours of steady light. Some of the sheets, by this process, showed a heavy impression, others rather less, and still others only a very light impression. To bring this out, pyro soda is useful with some bromide of potassium. The result of these experiments was unimportant from beginning to end. On no one plate had any reduced effect been produced; and a distinct discolouration of the plates, as I had obtained with tin, could be still less expected here. I merely mention that I had no better success in the same treatment with optical glasses of brass and steel. I found no inducement to continue my researches in this direction.

"If any one concludes that the same is true in regard to gelatino-bromide emulsion of tin, he is very much mistaken. My remarks on this subject should prove the contrary by my various experiments with tin; besides, I am far from wishing to write, in this work, of the dark rays of tin. It has rather to do with electro-chemical effects which take place between the metals and silver alloy.

"To a better understanding of my remarks, I will place the results of my researches in the following order: On two glass plates rubbed with weak gelatine bromide silver (ultra-violet sensitive plates of my restoring process), I lay in dark-room light two thick tinfoil frames. To obtain a close contact, the plates and foil in the copy frames should be firmly pressed together. Then I place one frame in daylight, the other is exposed in the dark. After a few days each plate shows an almost perfect black impression of the foil. The foil itself has taken on the black spots of the plate; it has lost its mirror-like smoothness, and is of a dirty grey colour. The impression of the one exposed to the light differed very slightly. The light has consequently not acted upon the impression visibly.

"That the tin had acted in a far shorter contact I perceived by developing such a contact plate. I make this exception to the unlooked-for appearance of my experiment to the lower part 1000 ÅE photographic rays.

"The already-used plates must be covered almost to the full spectrum of a corresponding rectangle. I chose one with a fitted segment between the cassette wall and tinfoil plate of the whole size of the plate. During from half to one and a half hour's pressure, the plates and tinfoil are in an atmosphere of hydrogen gas under a pressure from ten to twenty mercury columns. The duration of the contact was longer than the exposure to the light. I make the exposure longer, especially the exposure secondary, as the spectrum rays have not acted to a certainty on the tinfoil.

"Then there, where the spectrum band falls on the tinfoil (that was on both sides of the segment), no visible effect was ever produced. The

plates were coloured, with few exceptions, when the whole space was disclosed, only near the edge, which was surrounded in larger or smaller spaces with peculiarly formed spots in lined succession. In the centre of these spots could be distinguished small silver shining rings with a high light of the colour of the negative. Feathery shapes passed through the high light like rays coming from the centre, which, however, were produced by the metallic residuum under the action of the tinfoil in the electro-chemical process and the development of salt crystals. The spots are of several sizes. Some are as broad as the plate and disperse in the form of tiny flames; most of them seem like little aureoles around the shining ring.

"Nowhere is formed a correct impression of the tinfoil layers. This circumstance should not appear strange, as an intense pressure of the plate on the tinfoil, as in copy frames, was not to be obtained. In a striking way, the larger spots extended over the cut-out segment where the direct influence of the tin was impossible. I surmise that in the contact they receive the ingredients of tinfoil (SnCuPbFeNi), and the silver haloids pictured in the development are spread over the plate and also over the cut-out segments, and have taken on the colouring of the unlighted remaining suffusion. It is less easy to explain where, on the contact plate, the necessary fluid acts in the electro-chemical process, for the plates are well dried and kept particularly from dampness. That the hydrogen gas which followed the exposure should be used for that purpose is not probable. On the other hand, the remaining ones without the tinfoil sheet, there, where they lay on the edge of the metal case, also show spots. That in truth a fluid has formed between the tin plates seems probable, as they cling so closely together after the exposure, quite as though they had been glued.

"It may seem that these spots are surface blemishes of the plates or the work of pressure, but those produced by tin are so radically different from surface defections and from the colouring of those produced by pressure that the confusion of the two is impossible.

"I did not pursue these experiments further. Therefore, as they resulted solely as sporadic appearances of other observations, they can raise a slight claim to integrity. What remains for me is to remark on the sameness of both Mr. Russel's experiments and my own. But at the same time this also shows how carefully one must go to work for an explanation of supposed photographic light workings if one does not wish to run into the danger of mistake in the work."

#### MR. A. BOGARDUS ON THE SITUATION.

THE veteran contributor to the *St. Louis and Canadian Photographer* thus delivers himself of sundry ideas in a recent number of that magazine:—

"The writer is about tired of badgering self-constituted critics. They still continue to 'say on' and will, 'until death do us part.' It may be that they are not good for anything else. The vast multitude are too busy to give much attention to any one man's opinion. Very few have ever read a president's message entire.

"Our English contemporaries are filled with reports of the meetings of their numerous societies. The British Isles seem to have enough societies to give every man an office, and make him happy thereby. May they all prosper, and each and all dispense information, good dinners, and prime cigars to every attendant.

"It is hardly worth while to worry much about paper trusts. The world is large and full of live men. Paper will be furnished for use and all demands supplied. Attempts to monopolise the world's needs may work for a time, but in time they will be upset and the world will go on as if they had never existed. Noah once had a monopoly of the water, but there are plenty of boats that plough their way over the vasty deep nowadays, fare low, accommodations good, and return tickets half price. Tennyson says:

"The world, the world,  
All ear and eye, with such a stupid heart."

"It is not worth while to attempt photography with either a stupid heart or a stupid head. To succeed, the party must be on the alert, quick to perceive, quick to remedy. Without these, everything will run loose, even hopes and expectations, results will never be success. It is common for a family to show impressions produced by Alexis with his camera, and tell how successful Alexis is. Your practised eye tells you that there is not a good picture in the lot. Alexis needs the 'know how' just as much as he needs his camera.

"Some game is not worth the powder. Learning to be a good photographer is worth all the care, skill, and attention you can give it. While you are expending these, you are not wasting ammunition on worthless game. Your money may be lost. The devouring flame or the cyclone may destroy your property, but acquired knowledge will remain with you as long as life and health shall last.

"Money makes the mare go, but sometimes the mare runs away. A clear head, a clear conscience and willing hands will bring the needed money. It goes fast enough itself without spending it on the above-named biped. Keep a good grip on it.

"There's many a slip 'twixt' the box of plates and the finished

picture. Most of the 'slips' are from carelessness or want of judgment. Of course, the plates or the chemicals get the blame when the innocent things are doing the best they can do under the treatment they are receiving. Failures, like successes, are in most instances home-made.

"The neighbours were invited to see whether the rigidly posed, newly painted portrait looked like Marier. It was yes and no, yet it was framed and hung until the next generation considered it too old-fashioned for their parlour. Then it was put in the garret to be used as a target for the arrows of the grandsons, who tried to hit the old woman in the eye at ten paces.

"Photographs of lightning are genuine flashlight pictures. The flashes are of great variety, and always with black background. They must be curiosities to the bad mortals who are afraid to look when the sky is in action and the display gorgeous."

#### DEVELOPING KODAK FILM UNCUT.

[Price paper in the *Photo-American*.]

If film is cut into strips and thus developed, there are several mishaps liable to occur, viz., 1, uneven development, spots, &c., caused by developing several strips in the same tray together, the films often adhering to each other in spots, thus preventing even application of the developer on all parts of each strip; 2, tearing the emulsion by repeated turning of the strips, causing holes which spoil the film, or at least are hard to fill up before printing; 3, tearing in washing by rubbing against each other as the running water, so necessary to proper elimination of hypo, turns them around and against each other; and, 4, if pyro developer, which is the best, is used, a sadly stained hand at conclusion of the operation is inevitable.

For these reasons I do not cut my film into strips, but develop the whole roll at once, and, although I have as many failures as the average amateur, I do not have holes in my film, soiled hands, or any of the troubles common to the other method. I am entirely through, and have my film-washing in half the time it took me by the old process, and in every respect get the most satisfactory results I have ever had. In developing the whole roll at once it would naturally be supposed that all would be developed alike, and that attention to the necessary modifications of developer in order to obtain the best results from all on a roll which contains over, under, and correct exposures could not be given. Not at all; each separate picture is treated, if necessary, and the results are much better than any I have developed in small strips.

How do I do it? Why, I pin the film on a board, face up, and paint them with a wide rubber-bound camel's-hair brush, kept full of developer while brushing. It is as neat as it is simple, and, short of developing each exposure separately, is the most rational way of going about the work scientifically. The materials necessary are two boards four feet long, one for developing and one for fixing upon; a two to three-inch rubber-bound camel's-hair brush, some developer, hypo, blotters, and absorbent cotton. From start to finish the fingers are not even wet with any chemical used; therefore, dear, nasty, old reliable pyro, which cannot be beaten for films or plates, may be used. I could write a long article based on experience, singing the praise of pyro, and could prove by negatives of my own and those of my friends that it has never been equalled as a developer; but, as that is not the subject I started on, I'll switch off. Before darkening the room (the bath-room, of course) I prepare two ounces of fresh developer and pour it in a small tray. In another tray or saucer I have old developer, and in still another ten per cent. bromide of potash solution. There is also a bottle of hypo solution with a goodly tuft of cotton handy. Now darkening the room and lighting my lamp, I spread clean blotters on my developing board, which is of half-inch clear pine, four feet long and one foot wide, and, unrolling my film, pin it, face up, on to the board, two pins at each end and two on the edge, about in the centre, being plenty. I generally develop two or three rolls of folding pocket Kodak film at a time. Now filling my brush with water, I gently brush all the film over, enough to soften the emulsion, and then in the same manner paint the strips with fresh developer, keeping the brush moving slowly over the film, enough to ensure its being moist with developer all the time. The over-exposed ones come up first, of course, and those are first swabbed over with bromide, and then kept wet with old developer and bromide alternately. I apply these with a tuft of absorbent cotton held on a stick with a rubber band, stick and cotton to be discarded each day. The other films, meanwhile, have been developing nicely, and can be so manipulated that they finish with the rest, adding little touches of bromide, old developer, or alkali, as needed, with a round brush. The under-exposed films are given all possible encouragement by treatment with developer suited to their wants, and by a hot blotter of the right width slipped under them. This is a very effective accelerator, and helps the film as no amount of developer would. I keep a few blotters wound around the hot-water pipe in summer, or the steam pipe in winter, and thus have them right at hand. Those whose dark rooms have no such convenient arrangement can, doubtless, heat the blotters on top of the dark-room lamp. The films remain moist with developer nicely, and it is no trouble at all to keep them covered if well wet at first. I never had a case of spotting yet from unequal application of the developer by the brush, and I have developed

a large number of rolls in this manner. In winter, if the film is brittle, a drop or two of glycerine in the developer will be found excellent. There need be no hurry, no worry about results, and an easier way of improving a negative by local treatment could not be imagined, as it all lies before the operator as plain as a picture, and the spots which need bringing out or retarding, as the case may be, show plainly. In developing a number of strips at once in a tray, one cannot stop long to doctor little patches, because the other films need constant turning; so all get the same treatment practically, and we all know what the average is by such a manifestly imperfect method. Having finished developing, remove the pins, and, with a bit of blotter grasped between thumb and finger of each hand, remove the film to the other board, which is not covered. Pin it down securely, using about eight pins, and put it in the bath tub under the tap to clear it of stain. After a few moments remove it to the table and mop it over gently with a large swab of cotton containing all the hypo it will hold. Continue to drag the swab of hypo over the film, taking fresh solution as necessary, until it is completely fixed, which can be ascertained by unpinning one end and examining the back. I purposely do less swabbing at one end, so that, when that end is found to be fixed, it can be depended upon that the whole roll is. This saves examining more than a couple of inches at the end.

When this part of the work is complete, I place the board in the bath tub, film down, and let it float upon the surface of the water, which is kept changing. If the weather be warm, the film can be painted with alum solution during any stage of the performance. It is well to do this after fixing always, even though not apparently necessary, as the film may soften in the wash water. Washing is very thoroughly accomplished in fifteen minutes. Everything upon the film which we wish to wash off, the hypo, to wit, is heavier than water, and consequently falls off better in the tub when on top of the water than it would were the water on top of it. If the film was much under-exposed, and prolonged development has left it considerably stained, it should be painted with a weak solution of tartaric acid after washing a few minutes. A saltspoonful of the powdered acid to a cup of water, or, to be more exact, two grains to the ounce of water, will be strong enough to remove the greater part of the stain. All the stain should *not* be removed, especially from a thin negative, as the colour in the film helps the printing in the shadows. After the acid treatment the full amount of washing should ensue, when nothing remains but to swab the film with glycerine solution, made of glycerine, quarter fluid ounce (a teaspoonful will answer); water, eight ounces or one half-pint. After swabbing this solution over the negatives two or three minutes, stand the board on end in a dry but not too warm room until quite perfectly dried. Then throw away the mixed developer, swabs, also the blotters, if much soiled, wash the developing brush well, and all is through with. There is nothing to clean up, no mess of any kind, fingers are as dry as at the commencement. Each board must be marked, and always used for the same operation. This method has also the advantage of being the most economical of any, for very small quantities of developer are used, as will be noticed. I have never had occasion to use wider films than bull's-eye  $3\frac{1}{2}$ -inch, but I should not hesitate to use the same method on films of any width if I could get a soft brush wide enough. I believe this method of developing will be new to a majority of the readers of this JOURNAL, and, though it is often truly stated that amateurs should steer clear of new things photographic, I can vouch for this one, as it has been in use at my house over a year. Ladies will appreciate its cleanliness especially, though many men have as much dislike of nasty stains on the hands as the next person. The films are so clean and perfect too, free from defects such as holes, scratches, and tears, which are almost unavoidable by old methods; they are a real pleasure to look at. It is an ideal method, and well worthy of adoption by all who use films.

L. JARVIS.

#### IN BROADLAND.

In a recent issue of the *East Anglian Daily Times* (Ipswich), a well-known literary and musical critic, writing over the signature of "Lounge," draws the following charming pictures of the Broads, a part of England so much in favour amongst photographers:—

"The Broads once more! No schoolboy, the journey money in his pocket, ever desired to shout in triumph more eagerly than I, as the splendid Cromer express, with which the G.E.R. has now brought Poppyland and Broadland to the doors of all the world, set me down, hot, thirsty, but happy, at Wroxham Station. Books, music, and all the other stern facts of life were left behind; and, inasmuch as at least seven years had gone by since last I set foot, so to speak, on the Broads, and in these years I had accomplished a small odyssey in many lands, I was anxious to see how far my old recollections would accord with the new impressions, for the Broads as a holiday haunt had been my earliest love—a calf-love, if you will, to begin with; but it had lost none of its strength in succeeding years, and now I wondered if a more travelled eye would find the same charm and romantic quiet that had of old seemed to invest every part of those placid waterways. Changes there must needs be, of course, for the tripper and the speculator are abroad, and the very railway facilities which enable the true lover to attain his felicity more easily also bring a horde of cheap and noisy

tourists, who are neither decorative nor sympathetic. Tales, too, had been told me of the gradual encroachments on the public privileges by greedy landlords, and I almost wondered if any Broad were left on which one might sail unchallenged. But, for the moment, it was enough to be once more at Wroxham, where my host awaited me to lead me gently on board the *Leisure Hour*, most comfortable of wherries. Already it was plain that even here civilisation had set in with something like severity. A fakir, in the dress of the Suffolk rustic, sold 'hokey' by the dusty roadside, advertising his fearful wares in cries of exceeding hideousness; 'Universal Providers'—unconnected with him of Westbourne Grove—offered everything that a yachtsman could desire, save only fair winds and weather; and, pleasantest change of all, one found that the quaint and comfortable Horse Shoes Hotel had passed into the hands of the genial George Smith, whom I had learnt to know, at Brundall and at Oulton, as an excellent provider of dinners for those who had grown weary of the tinned foods that, after a week or two, seem to grow so appallingly in tinniness. For half a mile below the bridge the river was crowded with all manner of craft, huge wherries, yachts of varied tonnage, skiffs, and launches of many shapes and sizes. And there, flying her blue and yellow pennant, lay the *Leisure Hour*, twenty-five tons register, and classed A1, not only by Grimsell, of Reedham, her owner, but by all who knew her comfort. . . .

"Leaving the river with its Saturday trippers, we turned the sudden corner that leads into Wroxham Broad, and dropped anchor in the silent water. Hardly could you discern a trace of human existence; the farm buildings at the south end were apparently deserted, and the single wherry that had preceded us was all but hidden in its corner as we crept noiselessly along. Not even a fisherman was in sight, in this famous haunt of pike and tench; but, before we had snugged down for the night, a boat appeared from nowhere, and half-a-crown was demanded in the name of some unknown owner. Then it appeared that the Broad had now two owners, and the line of division was indicated by two white posts, bearing notice-boards that could not be read at three yards' distance. One proprietor we knew—Ellis, a farmer and sportsman of great knowledge; and, since it seemed that we were but a few feet from his half, we hove our anchor and drifted across the line into our friend's water, leaving the representative of the unknown to depart uncrowned. Had we crossed the line as we swung at anchor, I do not know what would have happened, but I suppose that assessors and surveyors would have been called in to decide how many pence were due to each proprietor. And then it was dinner-time, and a cook who, within his not very narrow limits, was a man of excellent resources, spread a table in that pleasant wilderness which would not have disgraced many a club. The blazing heat of the day was followed by a very misty night, with a pale moon rocketing through driving clouds; and, when you turned out on deck for a moment, your shadow made strange Brooken spectres on the whirling fog. But what matters fog when you have a snug saloon, a pianoforte, and two ladies to play the violin to you? Thereafter came that happiest of all sleeps that is known only to those who have been cradled in yachts; and it seemed but five minutes till the swish of water on the deck told that a new day had begun. It was Sunday, and there was more than a Sabbath stillness over the glassy Broad, where each water-lily and sword-like gladden found its perfect image. A reed-warbler balanced himself sideways in the reeds, and talked cheerfully; a coot came silently from his nest, and fled, as three Adamo figures, not without prophetic shivers, emerged from the cabin and flung buckets of chilly water over each other; for swimming in fresh water is an abomination, and three or four buckets of fresh water, if you stand up to them manfully and unafraid, are a joyful beginning to such days as we were to spend.

"Monday morning sees us, after certain necessary purchases of fresh meat, eggs, and vegetables, starting for Heigham Sound. All goes well till we are past picturesque Horning, where dirty children, visibly embodying the results of cheap education, run along the bank, dolefully chanting 'John Barleycorn' in the hope of backsheesh. By the time we reach the mouth of the Ant, however, the tide has turned, and the wind is contrary. There is no hope of reaching Heigham Bridge that night, and we anchor just opposite the crumbling ruins of St. Benet's Abbey, the home of many loquacious jackdaws and starlings. Fifty yards astern is the dyke that leads to South Walsham Broad, whither we pull after dinner in the cool of the evening. For me this is the most beautiful of all the Broads, especially when you make your way across the larger lake and push on into the inner Broad. The hand of the spoiler is at work here; and, though I believe that as yet no attempt is made to enforce legally a demand for payment, a notice-board, marked 'Private,' at the entrance is a prophecy. I express no opinion as to the legal rights of the principal landowner here, but I confess I would give a good deal to know by whose authority the public staithe is practically blocked with the bulk of an old wherry. There can be no possible question as to the public rights in that staithe, and the blockade should be made a matter for public protest at once. Of course, nothing will be done; there seems to be so utter a lack of public spirit in those who are on the spot that the insidious beginnings of encroachment are allowed to go unchallenged. The small tenants—I am not speaking now of Walsham Broad, but of the question as a whole—are afraid, in many cases, to give evidence against their landlords; the yachtsmen and sportsmen, who are

most interested, are a scattered tribe, amongst whom it is very difficult for obvious reasons, to establish any solidarity of interest and action; and it is already plain that, in another twenty years, the Broads, as we of this generation have known them, will practically cease to exist. When the test case of Hickling Broad was fought, all the weight of competent evidence that was brought forward failed to convince Mr. Justice Romer, and we—the public—were awarded only the sailing rights, the fishing and shooting rights being lost for ever. There is a tradition current now—I give it for what it is worth—that this same learned Judge, after the trial of this case, paid a visit to the Broads, and that, having examined the matter for himself, he found reason for changing his opinion on the whole question. His judgment, unfortunately, cannot be changed, though hundreds of yachtsmen are as certain that the water in Hickling is tidal as that it is tidal in the Orwell. Well, public apathy has its own bitter reward, and those on the spot who might have prevented these losses of privilege and pleasure will repent too late when, with the Broads practically closed to, and therefore deserted by, the public, they find their properties depreciated and many sources of income reduced or extinguished.

"Heigham Sound is held by some to be the most picturesque part of the whole district. That opinion I do not share, for I confess I tire soon of these grey wastes of reed and gladden. Wild it certainly is, and worth seeing; but, after a single day spent in its cold monotony, I long for the more peaceful and dreamy variety of water-lilies and willows, and the wide, unfurrowed mirrors of Walsham and Wroxham. But the Sound is a convenient starting place for Horsey Mere and Wroxham, though the dyke that leads to the latter is now so foul with weeds that only the lightest of craft can navigate it. Weary work it was to pull and push our heavy centre board dinghy up that bewildering desert of weeds; and, when at last we reached Wroxham, it was to find impertinent notices that declared even the old gap through the sandhills to be 'private.' Lying that night below Heigham Bridge, to be ready for an early start for Yarmouth the next day, I fled across, by train, to the bloated town to look for letters, newspapers, and other signs of a half-forgotten civilisation. Just twenty minutes had I in the town before the last train started back; but the following afternoon saw us all lying by the old tower that marks the mooring-place of yachts in that unspeakably dingy river. In Breydon water a splendid breeze was blowing that carried us to St. Olave's in much less than an hour; and, though in sailing a wherry one has not the same sense of intimate connexion that comes when one's hand is on the tiller of a racing cutter, it was as fine sailing as one could ask. A wherry is heavy to handle in a strong breeze, and my personal comfort was not increased by the fact that the skipper, a man of short stature, had caused the rudder head to be shortened, so that he might lean on the tiller where his body was best fitted to the pressure. This brought it fully six inches too low for me, with somewhat painful results to my person; but that wild rush across Breydon still remains in my memory as a most exhilarating piece of sailing. At St. Olave's we found that excellent hostelry, the Bells, in new and very capable hands, and the luxury of cigars, coffee, and liqueurs were ours after dinner. A choir treat was in progress, and some capital singing was to be heard; and then there was a little dancing, and much genial merriment till far in the night. That night, too, was our last, for the next day found us on our way to Oulton and home. It was the best day of all, in point of weather, the last day of one's holiday always is. But there could be no regrets, looking back on such a week; for the physical beauties of the Broads are not, to my mind, necessarily their greatest charm. They are great, indeed, and nature speaks there with a voice so strange and new that, though all must hear and listen, no one has yet interpreted it with complete success. Not even Swinburne; not even my companion—the Dr. Emerson, who, in *Wild Life on Tidal Water, Life and Landscape of the Norfolk Broads*, and half-a-dozen similar volumes, has caught and recorded so many secrets of that wonderful life. He has crept closer to the heart of these things, their wildness and charm, than any other writer; but at the back of all is an incommunicable mystery, a soul that is revealed only in sudden moments, and lures the nature-lover to follow the flying feet. For me Broadland still remains, in spite of noisy trippers and tearing launches, one of the last strongholds of that elemental beauty which elsewhere is fast disappearing. The lagoons in Venice, Barbizon in France, the Broads in England—the same voice speaks in all for those who have ears to hearken."

#### AMERICAN DRY-PLATE MAKING AND DRY-PLATE TAKING.

[A lecture delivered before the Columbia Photographic Society.]

DURING the past few years photography has advanced with such giant strides, both from a practical and artistic standpoint, that it has hardly been possible for even an adept to keep pace with it. Every day makes it more difficult for one to enter the line with those ahead of him, and hence it may be assumed that a few hints, such as these are intended to be, may prove an aid looking toward successful results, and make easier a pathway strewn with trouble.

One of the truths just brought home to the venturesome tyro who invades the magic realms of photography is that there are a lot of

illusions to be dispelled, a lot of false impressions to be corrected, and, what is more to the point, a whole lot of serious study involved before one can take or make a good picture. The oft-used "you press the button" may go with the schoolboy who trusts to chance or favourable conditions to gather an occasional subject, or, with the young lady who cares not to soil her lily-white hands with chemicals, and looks to adoring and indulgent parents to "do the rest;" but let me assure you that, while the "press-the-button" theory has been the means of drawing into the photographic ranks thousands, many of whom have learned to their sorrow that the mere manipulation before mentioned does not entirely constitute photography, to produce the best results one must go about in the good old-fashioned way.

An axiom might be suggested to the effect that to take one really commendable picture is far better than to trust to the uncertainties of a dozen chance "shots," whether the medium be films or dry plates. There are numberless cases where anything but instantaneous work is impossible, but is simply a necessary evil. At the same time the tripod camera, combined with time and patience, a careful study of subject, light, and other conditions is unquestionably the only sure means of attaining the desired end. A professional photographer only "snaps" a baby because he has to, and not because he wants to, and you can easily determine to your own satisfaction that in any gallery he takes due time when he deals with those of the age of intelligence.

With this introductory regarding the making of dry plates a few points may not be amiss, especially in view that suggestions regarding their manipulation may follow in logical sequence. It is not to be doubted that the majority of persons have studied photographic chemistry, if only in a superficial way, and have a general idea of the means by which we obtain a dry plate. As a certainty, however, I will assert that few possess knowledge of the actual details regarding their manufacture on a commercial basis, or the care needed to be used, or the means taken to produce a merchantable article, and one which will hold its own beside other brands. If this knowledge prevailed, you can rest assured that there would be fewer complaints from the consumer, and a greater appreciation of and wonder at even the existence of such an article as a dry plate.

You can take it for granted that the perfect plate has yet to be made, the same as the perfect negative produced or the perfect print toned from it. Were it not for the possibilities to be obtained, photography would cease to be an art.

The manufacturer of a dry plate has many things for which he is to be blamed, no doubt; but the category does not include everything. It can be asserted positively that the party who attempts to place a defective plate on the market simply commits suicide, in view of the existing competition and demand for only a first-class article. The glass used must be of the best and free from bubbles, the right substratum employed, the emulsions uniform, the speed fully maintained, and the developing qualities of a simple nature, the resulting plate one that shows fair results under almost any conditions of light and shade. To produce such an article means work that the average photographer usually fails to comprehend. The emulsions are made up a couple of weeks ahead, tested many times, filtered twice or thrice through chamois skin to ensure positive freedom from dust, kept at a uniform temperature while being flowed, and again tested after being dried. The finished plate is subjected to ruby light at least seven or eight times before finally packed.

In this connexion I beg to state that the light employed in a dry-plate factory is deep ruby, and *never* a combination of orange and ruby. The average photographer uses more light in a small dark room than is employed in an entire factory.

Dry plates are simply fed upon travelling tapes, which pass under a small silver tube, having a slot in it which permits the emulsion to flow through, and then are immediately drawn over ice in order to set the emulsion. This latter object is attained within a few feet, and an employé there stationed picks them up, places them in racks upon a truck, which is wheeled into the drying-room when filled. Here another important point is involved, as the plate takes from three to four hours in drying, and the temperature, if allowed to check this drying by only a few degrees, the result shows a stain that simply spoils them, and which cannot be removed. Another factor is the air used, and it must constantly be changed. Usually the air is drawn from a tall chimney, drawn through water and dried over steam pipes before being used in a factory. The floor is also sprinkled in order to avoid dust being circulated therefrom. The employés are compelled to wear rubber-soled shoes, and everything is done in the power of man to obviate the slightest particle of dust or dirt being raised.

Plates are usually coated in large sizes, assorted, and cut down to the smaller ones. An 8×10 plate thus yields not only 5×8 but the 4×5 size. Extreme care is always necessary in the cutting room, as particles of glass not removed at once can easily spoil the next plate. Another point that must be considered by the manufacturer of dry plates is the risk incurred in shipping them to their destination. If they are forwarded by rail, they may be packed alongside of coal-oil products, and are thus irretrievably ruined; if shipped by steamer, they may encounter water in the hold of the vessel, or, if on the upper deck, encounter a wave that will also render them useless. It may not seem amiss for me to reiterate here the fact that it must seem to the educated photographer a wonder that

dry plates have ever reached their present condition, or existed at all, in view of the difficulties attending their manufacture.

It is with reluctance that the second part of this subject must be approached, if only the simple reason that more depends upon the intelligent handling of a plate than upon its manufacture, which is worked out upon a scientific and exact basis, tested by experts, and never placed upon the market by any reputable manufacturer without being fully up to grade, and equal to all demands that might be placed upon it. As to exposure, the fact has been proved that judicious development can alone bring best results. The late Professor Newton, in my own presence, took over seven hours to obtain those famous negatives of the Hell Gate explosions, while, on the contrary, over seven hours' exposure was required to make a picture of the interior of Trinity Church in New York, with but a short period of development.

It is a matter of regret to all manufacturers that so many persons rely upon snap-shot work instead of the old tripod-camera business, and I take extreme pleasure in reverting to this fact. Why persons should risk so much to obtain so little is a wonder that cannot be explained. Our best view photographers often study a view for weeks from "every clog of vantage" before they will even expose a single plate. Why, therefore, expect to make a dozen immaculate photographic views in a single afternoon, and then blame the manufacturer of plates or films because you do not obtain a dozen perfect negatives?

Photography is a study, deep as any science known, with under-developments on all sides, over-developments on the part of the unthinking, and with possibilities so far buried in the future that none can fathom them. Do not labour under the impression that the changing from one camera to another may mean success, or that if you had this or that lens, you could gain the ideal, or that, one developer is so much better than another, that to use it will place you upon the topmost pinnacle. Use what you have, adhere to what you have, study what you have, and you will learn the lesson, attain the success, make photography a pleasure to yourself as well as a lesson in a noble science to your friends.

WILLIAM F. MILLER.

#### THE ACTION OF NASCENT SILVER IN DEVELOPMENT.

DR. KARL SCHAUM in his paper published at p. 469, vol. xlv. of THE BRITISH JOURNAL OF PHOTOGRAPHY, referring to the building up of the developed image, appears to suggest that the bulk of the silver forming the negative is produced by reduction from the unaffected silver bromide in the non-image, the additional silver being deposited upon the silver of the image. I believe that this theory has frequently been put forward, but I have never been able to understand how such action can take place with alkaline development, unless the developer contains a solvent for silver bromide, and the presence of a solvent does not appear to be essential to the attainment of density. Further, Dr. Schaum seems to misinterpret the subhaloid theory in suggesting that under it an exposed and fixed plate should be developable in an ordinary developer without any silver. The fact that an invisible image, amenable only to a process of silver intensification, remains after fixation, appears to me to be strictly in accordance with the subhaloid theory, which also seems to afford a satisfactory explanation of the manner in which density is obtained in the ordinary process of development, quite independently of the existence of the unexposed particles of bromide in the non-image.

Consider the case of two adjacent particles, one in the non-image and one in the image. The two are separated by intervening gelatine, and while one is totally unaffected by exposure the bromide in the other has been partially reduced to a subsalt. There is no reason that I can see for supposing that the whole of the exposed particle is converted to a subsalt, the contrary is indicated by the fact that both particles practically disappear in a fixing bath; and, further, the opacity of the particle should prevent the light from reaching every molecule of it. It may reasonably be assumed that only the outer molecules of the exposed particle are affected by light, so that it consists of unaltered bromide surrounded by an outer skin of subsalt. On the application of the developer this subsalt is reduced and nascent silver is produced in contact with the normal salt in the interior of the particle, and the immediate result of such action can apparently only be an increase in the amount of subsalt, for presumably the reduction of a molecule of  $\text{Ag}_2\text{Br}$  in contact with a molecule of  $\text{Ag}_2\text{B}_2$  must result in the production of  $2\text{Ag}_2\text{Br}$ . It would appear that this process must continue until the whole particle is reduced to subsalt, after which the production of metallic silver in a permanent form would commence, and continue until either development is stopped or the whole particle is reduced to silver. Density will thus be obtained by the reduction of the normal salt remaining in the exposed particle after exposure is terminated, and independently of the adjoining unexposed particle, which may remain quite unaffected, provided that the developer has no solvent power and is so adjusted and restrained as to be unable to exert any direct reducing action upon it during the time of development. The image is then built up, not by the deposition of silver upon nascent particles, but by the reduction *in situ* of the normal salt that happens to be in contact with the nascent silver produced by development. The application of a fixing bath before development results in the solution of nearly the whole of the exposed particle, only an invisible trace of metal

being left by the subalt. A feature of this theory is the non-production of metallic silver during the first stages of development. This might be tested by the aid of ammonium persulphate; I have not yet made any experiments in this direction, but, as it is well known that no free silver can be detected in an exposed plate, it would be useful to determine how soon after the commencement of development an appreciable quantity is present.

Experiments on the constitution of the exposed, partially developed, and completely developed image would, no doubt, be more easily conducted on an extremely coarse-grained slow film, if such can be produced by any modification of the ordinary process, and possibly an artificial emulsion, consisting simply of large solid particles of bromide imbedded in gelatine, would serve the purpose.

Dr. Schaum states that he failed to reproduce Eder's experiments in reducing a film at the points where a silver wire had been brought into contact with it *without pressure*. Does not this appear to indicate that pressure is the cause of such reduction effects? With regard to Dr. Eder's experiment on a thick opaque gelatine emulsion, I have always been inclined to doubt the possibility of securing absolute opacity in a substance formed under the conditions of a gelatine emulsion, and Dr. Schaum seems to be of the same opinion. C. WELBORNE PIPER.

### LEEDS CAMERA CLUB ANNUAL EXCURSION.

THE present flourishing condition of the Leeds Camera Club will, no doubt, receive an additional impetus to its title to rank as one of the most successful amateur photographic societies in the North from the exceedingly well-planned and enjoyable excursion held on July 26, on the occasion of the Club's annual outing to Chatsworth and Haddon Hall, when the members and their friends, to the number of thirty-five, including a fair sprinkling of ladies, took advantage of the unusual privileges offered by the Secretary and President, who had the arrangements in hand.

Leaving Leeds at 8.50 a.m., Grindleford Bridge was reached *via* Sheffield at 11 o'clock, where two pair-horse waggonettes and a *char-à-banc* were in waiting to receive the party. The weather was dull at starting, but ere long the sun found glint through the sky, and, though at times rather threatening, yet delightful atmospheric conditions prevailed during the remainder of the day. After an hour's refreshing drive the conveyances reached the pretty village of Baslow, where, a private-gate ticket having been secured, the party entered Chatsworth Park by a near route, and a short drive brought the enthusiastic amateurs to the house, the princely seat of His Grace the Duke of Devonshire, K.G.

By the courtesy and kindness of Mr. Gilson Martin, chief steward, the members were shown over the house in one party, and afterwards were allowed the unusual privilege of taking pictures in the private grounds, a favour which was immensely appreciated, and cameras were soon at work securing many a lovely bit of those interesting and well-favoured grounds. The Fountains, as well as the Great Cascade, were also specially turned on for the benefit of the Club, and the large Fountain was photographed sending up a jet of water close on 300 feet in height.

After a couple of pleasant hours, gone only too quickly, a return was made to Baslow, where lunch was had at the Wheatsheaf Hotel, and the party again joined the waggonettes. Bidding adieu to Baslow, the drive was resumed by way of the model village of Edensor and Rowsley to Haddon Hall, undoubtedly one of the most perfect specimens of mediæval domestic architecture extant. Here the party separated into twos and threes for a little serious photographic work, the chapel, ball-room, and terrace receiving special attention by the members. Following, tea was hurriedly disposed of, and, mounting the brakes, the home journey was begun, the return train leaving Rowsley at 6.42.

It was generally felt that the time was insufficient to admit of anything like proper attention being given to the many excellent subjects both at Chatsworth and Haddon and the district generally, and many a member was heard to express a wish for a further acquaintance with the neighbourhood. Leeds was ultimately reached about 10 p.m., the whole party having thoroughly enjoyed a most delightful and interesting day's programme; and the occasion will remain as a pleasant remembrance of the good comradeship that exists in the Club, and to be talked of many times during the forthcoming winter session of 1899-1900.

## Our Editorial Table.

### THE NO. 2 FOLDING POCKET KODAK.

Manufactured by Kodak, Limited, 43, Clerkenwell-road, E.C.

Messrs. KODAK, LIMITED, are introducing a new Folding Pocket Kodak which takes pictures of the size of  $3\frac{1}{2} \times 4\frac{3}{4}$  inches on the ordinary No. 2 bull's-eye spool. In addition to this feature, there is the convenience of

the camera folding up to dimensions which admit of its being comfortably carried in any ordinary coat pocket. In appearance the new Kodak resembles the No. 1 Folding Pocket Kodak, and it is somewhat less in thickness. It is also provided with tripod screw socket, and is therefore equally adapted for hand and stand work.

When folded, the No. 2 Folding Pocket Kodak measures only  $1\frac{1}{2}$  inches in thickness, while it weighs only 16½ ounces. It carries a spool of film for twelve exposures. The shutter of the No. 2 Folding Pocket Kodak is the same as that adopted in the No. 1 Folding Pocket Kodak. It is always set, and separate levers are provided for time and instantaneous exposures. A third lever regulates the stops, of which there are three.

### PHOTOGRAPHING: SIMPLE INSTRUCTIONS HOW TO DO IT.

50 pp. Price 3d. By the Editor of Photography. London: Hiffe, Sons, & Sturmeay, Limited, 3, St. Bride-street, E.C.

It is not an easy task for the photographic journalist to write down to the level of those who know absolutely nothing of photography, and at the same time to make clear to them the elements of the subject. The temptation to take refuge in the brevities of technical terminology is at times irresistible, but in the little book before us Mr. Child Bayley has successfully avoided it. To nothing but a photographic Mavor can it, in our opinion, be more fitly compared; for the instructions are simple, the language clear, and it thus constitutes a useful introduction to the practical study of photography. There are seven chapters, and the descriptive accounts of the various items of photographic apparatus, manipulations in development, and so forth, are plain and to the point.

### THE RÖNTGEN RAYS IN MEDICAL WORK.

By DAVID WALSH, M.D. 258 pp. 103 illustrations. Price 10s. 6d. London: Baillière, Tindall, & Cox, 20-21, King William-street, Strand, W.C.

DR. WALSH's book has run into a second edition in less than two years—a sufficient proof of its use to medical men. The first seventy pages of the work are occupied by a full examination of the electrical apparatus and methods available for the special needs of medical radiographers, and then for the remaining 170 pages we have the medical and surgical applications of X-ray work exhaustively set forth and very liberally illustrated. Dr. Walsh has evidently been at great pains in selecting the numerous cases drawn from actual medical and surgical practice in which the practitioner has found it of advantage to call in the aid of radiography, and the result is what we should imagine must be a reference book of the highest value to those engaged in the healing art. A large number of the illustrations are full-page, and all of them are very informative. The book is well produced, and altogether it strikes us as a most useful addition to X-ray literature, and one, moreover, that even a layman may study with profit and advantage.

### CHIMIE DES MANIPULATIONS PHOTOGRAPHIQUES.

Gauthier-Villars, Masson, & Co., Paris.

THESE two small volumes by M. G. H. Niewenglowski form part of the *Encyclopédie Scientifique des Aide-Mémoire*. Vol. I. deals with the negative, the processes of development, fixing, reduction, intensification, &c.; and Vol. II. with printing processes, toning, &c. The volumes are very compact, and the subject-matter well arranged.

### KATALOG PHOTOGRAPHISCHER APPARATE UND UTENSILIEN.

R. Lechner (Wilh. Müller), Vienna.

THE well-known firm of R. Lechner, Vienna, has sent us their catalogue of photographic apparatus, &c., and for elegance and completeness it has few rivals. Most of the articles are illustrated and described in detail, and an inquiry sheet is provided upon which the customer is invited to send particulars of anything he may require. Numerous process prints from photographs taken with apparatus supplied by the firm are also submitted.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Anderton's Hotel, Fleet-street, E.C., Wednesday evening, August 9, at eight o'clock. Members' Open Night.

THE Departmental Committee appointed by the Lord President of the Council to consider the question of the reorganization of the Education and Science and Art Department consist of Sir Horace Walpole, K.C.B. (Chairman); Sir G. W. Kekewich, K.C.B. (Secretary of the Education and Science and Art Department); Captain W. de W. Abney, C.B. (Principal Assistant Secretary of the Science and Art Department); Mr. S. Spring Rice, C.B. (of the Treasury); and Mr. W. Tucker, C.B. (Principal Assistant Secretary of the Education Department).

M. EMILE ZOLA, while awaiting with intense eagerness the issue of the Dreyfus court-martial at Rennes, is busy in his country house at Medan over the snap-shots which he took in London in his character of amateur photographer as well as searcher after human documents. His collection of photographed scenes and persons is varied and interesting. He has hotels, bridges, public-houses, and an assortment of the tatterdemalions and castaways who are, he says, so numerous in London. M. Zola laments that he lost several shots, notably one of a flower shop, where he bought bouquets every morning for his wife when she was ill.

MR. A. F. STANLEY KENT has been appointed Professor of Physiology in University College, Bristol. Mr. Kent received his scientific training at Oxford, which he left upon being appointed demonstrator of physiology in Owens College, Manchester. In 1889 he was invited by Sir J. S. Burdon-Sanderson to take charge of the histological department at Oxford, to lecture on special points in physiology, and to assist in the teaching of general physiology. Since 1892 he has been assistant lecturer in physiology and histology at St. Thomas's Hospital, and has carried out a number of researches, the results of which have been published in various journals, proceedings, and reports.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
7.....	Borough Polytechnic.....	{ Excursion: Gomshall and Shere' Leader, A. Belding.
7.....	Croydon Microscopical.....	{ Excursion: Gomshall, Leith Hill, and Holmwood. Leader, F. J. Townsend.
7.....	Kingston-on-Thames.....	{ Excursion: Winchester. Leader, H. M. C. Sprunt.
9.....	Photographic Club.....	Members' Open Night.
9.....	West Surrey.....	Open Night.
11.....	Croydon Microscopical.....	Conversational Meeting.
12.....	Darwen.....	Excursion: Whalley and Mytton.
12.....	Kingston-on-Thames.....	{ Excursion: St. George's Hill, Weybridge. Leader, W. M. Robertson.
12.....	Manchester Amateur.....	{ Excursion: Hathersage. Leader, J. Wood Smith.
12.....	Oldham.....	{ Excursion: Whalley Abbey. Leader, R. T. Taylor.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 27.—Mr. P. Everitt in the chair.

Mr. Hodd showed the whole-plate negative which he mentioned at the previous meeting as having blistered after reduction with ammonium persulphate. He had pricked the blisters, and they now were scarcely noticeable in the print.

Mr. BANKS thought the cause might be due not to the hot weather, but to oxygen liberated during the action of the persulphate. If blisters were due to water having got beneath the film, soaking the plate in alcohol would remove them, but this treatment has no effect if the film has been raised by imprisoned gas.

Mr. S. H. FRY had recently been troubled by blisters occurring in bromide paper during toning in the acid alum bath. He thought this must be due to carbonic acid gas. Probably there was an alkali in the paper, which was decomposed by the acid in the toning bath. He found the best method to cause the gelatine to adhere to the paper again was to make two pricks in the print, one in front and one behind, so as to allow the gas to escape and water to take its place.

Mr. BANKS said the carbonate present in ordinary water would be quite sufficient to account for the liberation of the gas.

THE HON. SECRETARY, referring to a former discussion on the effect of placing a sheet of paper behind a backed plate, said it was a fact that if a piece of paper were placed on the backing, that portion of the negative would develop denser than the other part. This was owing to light reflected from the paper.

Mr. TRAPE admitted this would be the case if the backing were not effective, but otherwise it would make no difference. He had found that even tinfoil could be placed behind a well-backed plate without any effect due to reflected light.

A discussion arose on the recent introduction of a paper for printing in colours. This was thought to be a revival of an old process.

Mr. BANKS remarked that beautiful colours could be obtained on ordinary paper by the application of various salts of manganese, iron, and lime.

### North Middlesex Photographic Society,—July 24.—A discussion on IS HAND WORK LEGITIMATE?

was the subject for the evening. Mr. F. L. Pither, who was unavoidably absent, was to have opened the subject. In his absence, Mr. J. E. S. MUMMERY (the President) read a short paper which was sent by Mr. Pither, in which he maintained that hand work, given that picture-making was the object in view, was perfectly legitimate, bearing in mind the shortcomings and limitations of photography. Mr. MUMMERY followed on with a few notes on his own account, bearing out and extending Mr. Pither's views. Mr. A. H. LIEBET, who took up the other side of the question, began by saying the very question raised a doubt. The purpose of it was to modify the shortcomings of the sensitive plate, or the negative may have been taken under unsuitable conditions, or to produce something different from what was obtained at the time of exposure. If the particular view you want is unsuitable, owing to atmospheric conditions or lighting, take it another time, when it harmonises with your mood. You should not attempt to obtain by photography what we know is unattainable by its aid. To exhibit a picture showing brush marks or varnish on the print, and call it a photograph, is downright falsehood. The discussion was taken up by many of the members, Messrs. H. W. BENNETT, J. MACINTOSH, S. E. WALL, and others contributing, and got rather lively towards the end, the general opinion being that hand work, if confined to the negative, was allowable up to a certain point; painting in figures, &c., should be barred.

### FORTHCOMING EXHIBITIONS.

1899.

- August ..... One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C.
- Sept. 22–Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- „ 25–Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18–24 ..... Croydon Camera Club.
- „ 22–Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27–Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7–9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between July 17 and July 22, 1899:—

**DARK SLIDES.**—No. 14,656. "Improvements in Dark Slides for Cameras." M. C. RYPINSKI.

**LENSES.**—No. 14,672. "Improvements in Devices for Observing or Reproducing the Images Projected by Optical-lens Systems." E. ABBE.

**CAMERAS.**—No. 14,705. "Improvements in Photographic Cameras." Complete specification. F. MERCEAU.

**CAMERAS.**—No. 14,743. "Improvements in and relating to Photographic Cameras." S. D. McKELLEN.

**X-RAY APPARATUS.**—No. 14,826. "Improvements in or connected with Apparatus for use in the Production of Röntgen Rays." Communicated by the Voltahn-Elektrizitäts-Gesellschaft A. G., Germany. W. P. THOMPSON.

**VIEWING PHOTOGRAPHS.**—No. 15,006. "A new Means for Viewing Photographs." A. C. PEARSON.

**BALLOON PHOTOGRAPHY.**—No. 15,011. "Improvements in Mechanism for taking Photographs from Balloons or Kites." G. M. HEATH.

**PLATE-HOLDERS.**—No. 15,065. "Improvements in or relating to Instantaneous Printing-plate Holders." Communicated by S. Maybell and M. Maybell. W. P. THOMPSON.

**ANIMATED PHOTOGRAPHY.**—No. 15,096. "Improvements in Animated Photography and in Apparatus connected therewith." A. M. BARNES and E. COWPER.

**SHUTTERS.**—No. 15,144. "Improvements in Shutter Apparatus suitable for Photographic Cameras." J. JENSEN.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### DEALERS' TERMS.

#### To the Editors.

GENTLEMEN,—May I, as briefly as possible, encroach upon your valuable space with regard to this subject. All the chemists in this town have now, and for some time, entered upon the photographic department, and apparently do a small trade in that line. I regarded the fact with more or less indifference, but felt, at the same time, that I ought to have taken steps to have kept pace with the times and gone in for the dealer's department myself. The circumstance which made me decide to do so is that a small stationer has now cut into the business, and tells me that he gets wholesale terms without question; but, on inquiry, I find that I am absolutely denied by the Manufacturers' Association the same terms which the veriest outsider can get, thus enabling him to cut into what I regard as a privilege that ought to be mine. I presume the objection is, that the photographer, as a consumer, shall not reap the benefit of "dealers' terms." My wife, as a professional musician, has no difficulty in obtaining full trade discounts on either sheet music or instruments. Why should there be such a marked difference in two professions similar in character? The draper possibly buys his materials upon trade terms, whether to sell over the counter as material or in the form of garments, the latter eventually possibly yielding two profits, which the Association's attitude would lead one to believe they think the professional photographer quite rich enough to do without.

I have recently had my premises enlarged, and many facilities made to enter upon the dealer's business, in the best of faith of becoming a dealer if I chose. Consequently I feel the disappointment. No one, of course, wishes to prevent my selling again, but the discount of ten per cent. given to me as a professional does not leave a very encouraging margin after carriage is deducted. It may be that I am ignorant of the qualifications necessary for a professional photographer to obtain dealers' terms, for there are many such. There is a business advertised for sale in *The British Journal of Photography* for the current week, with "dealers' discounts." Possibly one of your readers will be good enough to advise me.—I am, yours, &c.,  
A WOULD-BE DEALER.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

E. FENSKE.—Received. Thanks.

J. V. R. (Dublin).—We are much obliged for your interesting letter.

SOL RAY.—The *South African Photographer*, published by Messrs. Marshall & Brookes, Harp-alley, Farringdon-street, E.C.

W. H. BRISON.—We think you should have returned the camera in the first instance. Do so now, and you can claim the return of your money.

PYRO.—Better keep it in solution. By exposing to the air, it becomes partially converted into sulphate, which is the white powdery coating seen on the surface.

PYROXYLINE.—L. MOODY.—The sample of pyroxyline is quite unsuitable for bromide emulsion, or, indeed, any photographic purpose, for it is almost insoluble in a mixture of ether and alcohol.

COLLOTYPE.—A. L. As the ink obstinately refuses to adhere to any part of the film, it shows that the plate was under-exposed. Print deeper, and it may be well to increase the proportion of bichromate of potash.

LENS.—FOCUS. A lens of the type and focus you require, by one of our first class opticians, would probably cost you from 80s. to 70s. Most likely, it would have to be specially constructed, as it is not stocked by any, we suspect.

J. C. BAMLITT.—You appear to have fogged the plates during development. We presume they are first attempts! We should say there was nothing amiss with the apparatus. Careful study of an elementary book will put you on the right track.

VALIDITY OF PATENT.—DOUBT. Unless the specification describes the invention with such clearness that any workman with ordinary skill can work it, the patent is invalid. If the inventor has kept back any essential part as a secret, the patent is invalidated.

COPYRIGHT.—S. L. You cannot take action until you have registered the copyright. Under the circumstances, we doubt, however, if the copyright is legally vested in you. The negative is certainly your property, although you may not have a copyright in it.

CATHEDRAL GREEN GLASS.—S. BLACKETT. The tint known as cathedral green is difficult to describe in such a way that you would be able to select it with certainty. If you go to Hetley's, Soho-square, and ask for cathedral green, you will get the right thing.

COLOURING PHOTOGRAPHS.—ADA.—Messrs. Newman & Co., Soho-square, publish, or used to publish, a work entitled *Harmonious Colouring applied to Photographs*; better write to them. Wake's work has long since been out of print. That was published by us. It is, doubtless, the work your friend refers to.

EXHIBITION AND SALE OF PORTRAITS.—W. W. W. Certainly. Your customer can by law, as he says, prevent you selling copies of his portrait, or exhibiting them in the show-case, against his will, and you will find it a very costly matter if he puts the law in force. Don't you think it a very unwise policy to persistently give offence to sitters?

PRINTING TROUBLE.—BEGINNER. The fault of one of the prints is that the paper has not been pressed in places in close contact with the negative while printing. The other, the paper has been slightly shifted during the printing, probably when opening the frame to examine it. The remedy in future is obvious. No apology is necessary; we are always pleased to help beginners.

INVESTIGATOR.—1. We have failed to find the name of the agent, but we should imagine the goods could be obtained through such houses as A. E. Staley & Co. or Clement & Gilmer. Their addresses are in the ALMANAC. 2. At lower temperatures than 85° we have known films leave the support; on the other hand, we have developed some plates at over 100° without disturbing the gelatine.

NEMETO.—1. Our opinion of the trade in a town of the size you mention, and at the prices you propose to "cut," is that you would be worse off than you are at present. Your "cutting" notions entirely alienate our sympathies. 2. No; we do not think you would better your position. 3. The way to make money in photography is to open a cheap "quick return" business in a large industrial centre, or produce the very highest class of pictorial portraiture.

RESTORING LIGHT-STRUCK PLATES.—C. OLLIVER says: "I have about a dozen and a half plates that the light has got at, and fogged them. Can they be restored to their original condition, as I should not like to waste them?"—Yes; the method of doing it is given on page 1061 of the ALMANAC; but, with so small a number and so small a size, we should say they were not worth the trouble. Restored plates are generally found to be much slower than they were originally.

LENS FOR ENLARGING.—W. A. BAIN writes: "I have two lenses, an old whole-plate portrait lens and a whole-plate R.R. They both seem about the same focus. Which would you recommend me to use for enlarging from whole-plate negatives? Of course the portrait would be the quickest, but I want to get the best possible results."—By all means use the R.R., for, all things being equal, it will have the flatter field, and also give more even illumination at the margins of the picture.

FADING PRINT.—C. JOHNSON says: "I have an old photograph that has turned a little yellow, and, as the mount has been much soiled, and the picture was valuable to the family, I soaked it off, and remounted it on a new mount. When mounted, I was surprised to find that the print had faded very much and turned quite yellow during the operation—in fact, is spoilt. Did you ever hear of such a thing before?"—Yes, frequently; it is no uncommon thing for old prints that are soaked off their mounts to behave as the one referred to has done.

GLASS POSITIVES.—FIRST ATTEMPTS says: "Herewith some first attempts at glass positives by the collodion process. You will see that there are no whites in them, such as I have seen in some old pictures. The solutions are made according to the formula given in the ALMANACS. Can you tell me where I have gone wrong?"—Yes. The pictures are all over-exposed and over-developed. If they were a little more intense, they would be fairly good negatives. Give less exposure, and stop the development as soon as there is an indication of detail in the deepest shadows.

THE SOUTHAMPTON PROCESS.—J. CLARKE asks: "What is the peculiarity of the Southampton process for producing transfers? I refer to photo-zincography."—There is no peculiarity, inasmuch as it is one of the well-known methods of making transfers. Briefly, it is this: Thin paper is coated with gelatine and bichromate of potash. When dry, it is printed under the negative. It is then inked all over with transfer ink, and afterwards heated with warm water, which dissolves the unaltered gelatine, carrying the ink with it, leaving it only where the light has acted.

THE RULED SCREEN IN COPYING.—AJAX says: "I am much obliged for your reply to my query under the heading, 'Half-tone for Contact Printing. I am sorry to trouble you again, but will you tell me, Suppose I had to copy the enclosed print, would the use of a ruled screen give me a negative which would produce a better print than the original, i.e., would it break up the heavy shadows?"—Better make the experiment. Personally we have no experience with a ruled screen for the purpose. We should prefer to avoid the heavy shadows in the first instance, by a suitable lighting of the subject.

## EX CATHEDRA.

ALTHOUGH it is in its third volume, we have only this month seen for the first time a specimen number of the *Photo Era*, an illustrated monthly, published at 185, Franklin-street, Boston, U.S.A. The magazine is very tastefully produced, and the illustrations and letterpress make a distinct appeal to those whose sympathies lean towards the pictorial rather than to the scientific side of photography. In common with several of its American contemporaries, the *Photo Era* protests against a recent English criticism "that the American photographic journals get steadily worse and worse." There does not appear to be sufficient scope in the States for journalism of the kind with which English photographers are familiar, but we have not detected signs of decadence in the American publications that reach us; indeed, they appear to us to be improving rather than otherwise, and the *Photo Era* materially strengthens the favourable view we take of American photographic journalism as a whole.

THE issue of our contemporary, the *Graphic*, for August 5 contains reproductions of some of the photographers that won

prizes in the competition recently held by that journal. Commenting on fashion in amateur photography, our contemporary acutely remarks that it often happens that some prominent worker makes a successful picture out of, say, a cottage door, with a sun-bonneted peasant standing within its portals. Thereupon dozens of amateurs will aim at the same type of photograph, and the exhibitions are flooded with such rustic scenes. Last year there was a run on marshy land and lowering skies, with such titles as "When the day's work is o'er" or "Eventide," or a line from Gray's "Elegy." In the present competition "Mutton" would have been an appropriate title for hundreds of the pictures sent in, for their leading feature was sheep and lambs. Sheep browsing, sheep sleeping, sheep being sheared, sheep bleating along the dusty highway, and the same necessary animals in every imaginable position and situation came to us in droves.

\* \* \*

ANOTHER circumstance gleaned from a critical examination of the pictures sent in for the competition, adds our contemporary, is quite a curiosity of amateur photography. It would appear that certain workers who devote their attention to landscape are not as ready as they might be to recognise a failure when it comes their way. "What we mean is that, when a picture by over-exposure or wrong treatment during development becomes blurred or fogged, it is not discarded, but is preserved as if the fault were really a virtue, and with a high-sounding title such as *A Misty Morning*, or *Through the Gloaming*, is sent in for competition with works which have no such flaw. Photographs of this kind have before now been medalled by Judges who had a hankering after impressionism without that technical knowledge of photography which would have helped them out of the error. This circumstance has encouraged many amateurs to treasure their spoilt negatives instead of smashing them, as they ought to have done." We assure the *Graphic* that its remarks on imitation amongst amateur photographers, and the false value often assigned to spoilt negatives, will find general endorsement in the photographic world.

\* \* \*

THE successful competitors were as follows: First prize, 20*l.*, W. Maclean, Belfast, for *Worn out*. The second prize, 10*l.*, goes to Mr. Charles F. Inston, of Liverpool, for a seascape

entitled *The Storm Lifting*, the third to Mrs. Wiggins, of Salem, Oregon, U.S.A., for a rustic subject with the title, *Hunger ist der Beste Koch*, and the fourth to Alfred Craike, of Upper Tooting, for *If I had a Donkey wot wouldn't go*. The three-guinea Kodak cameras have been awarded, in addition to those in the present supplement, to W. S. Anderson, of Helensburgh, for *The Mouth of the Gareloch*, to Dr. A. Mazel for his landscape, *Près Randa, Zermatt*, to Seymour Conway for *Exeter Cathedral*, to W. G. Hooper for *Looking for the Postman*, to Mabel Thompson for *Setter Puppies*, to J. Redhead for *Ennerdale Lake*, and to F. H. Gardner for *Hoar Frost*. The winners of the one-guinea Kodaks, other than those specified in the present supplement, are Colonel Taylor, Dr. Wilbiral, T. B. Miller, F. A. Joyner, A. L. Spiller, G. W. Harker, P. Gay, of New Zealand, Miss P. Rochussen (Switzerland), Sydney Spencer, Mrs. Main, Miss Tremayne, and Rev. R. C. Macleod.

THE *Rochester Herald* (U.S.A.) contains the following report of a United States Patent Office decision relating to the methods of preparing sensitive celluloid film: "In 1898 Mr. Henry M. Reichenbach received a patent for the manufacture of a sensitive film on sheet aluminium. Mr. Reichenbach's discovery, which dates from 1892, was the fact that the celluloid could be coated and dried on aluminium without corroding the aluminium or becoming itself contaminated therefrom. Not long after Mr. Reichenbach's patent was issued, which was early in 1898, Frederick H. Kelley, of Pawtucket, R.I., filed an application for a patent on the same grounds as those presented by Mr. Reichenbach and demanded an interference with the latter's patent. The case was vigorously contested on both sides. More than a year has been occupied in taking testimony and the presentation of briefs before the Patent Office. The decision now rendered awards priority to Mr. Reichenbach, and fully establishes the right of the Reichenbach, Morey, & Will Company to the control of the invention."

THE *Camera Club Journal* for August contains some excellent contributions by Mr. Cadett, Mr. Percy Lund, Professor Norman Collie, and Mr. Albert B. Lloyd—photometers for colour photography, Wordsworth, Canadian exploration, and adventures with pygmies, supplying a wide diversity of subject and very interesting reading. The editor has the following vigorous rejoinder to some infelicitous criticisms of the *Camera Club Members' Exhibition* which appeared in the first number of a new photographic publication, *Camera Obscura*: "The paper on the *Camera Club Exhibition* is a most careless contribution. We are told therein that No. 97, which is attributed to Mr. Beard, is a portrait, is 'deeply, darkly, dismally dreadful—a black blotteque shadow, slightly relieved by jaundiced high lights,' with further high-flown criticism, including a dragged-in quotation from De Larochefoucauld, as to all of which we may remark that No. 97 is not a portrait, it is not by Mr. Beard, and *Mr. Beard has not contributed any portrait work*. It is the old story of the apology made by a Mayor to Queen Elizabeth for not firing a salute. The critic also tells us, 'Mr. Craigie shows several of his somewhat low-toned portraits, and also his well-known *May Time*.' "This is all right as far as it goes," as our friend, Mr. F. Braine, occasionally recites to us, only we may be permitted to observe that Mr. Craigie exhibits

only two portraits, one of which is particularly rich in tone, and informs us that *he has never heard of the above-named picture*." The Editor of the *Club Journal* also sharply criticises an American publication for treating somewhat perfunctorily of hand-camera work, and thus the number, as we have already said, makes good reading.

### LAC AND ITS SOLUTIONS.

In an article on this subject which we recently published we did not make any reference to the well-known preparation lacquer—that is, the fine varnish, which has lac as a basis, used in all optical instruments as a protection to the polished brass-work. If it were not for this lacquer, so fine in texture and laid on so skilfully as to leave no trace of a varnish having been employed, our lenses and camera fittings would, in a very short space of time, become dull and dark—in fact, so dingy-looking as to suggest at once something "second hand;" instead of which a carefully used lens looks as new and fresh at the end of quarter of a century as it did when it left the maker's hands. This is entirely owing to the brass after being brought to a high state of polish being dexterously varnished over with the thin, clear spirituous solution of lac, the coating being so hard as to resist a considerable amount of abrasion and rough usage, and, almost infinitesimally thin as it is, forming a perfect resistance against atmospheric action. Bearing this fact in mind, our readers will at once see how the different colours known as characteristic of the brasswork of various makers' instruments may be attributed, not to the quality of the metal, but to the tint of the lacquer employed. We are led to make these remarks by the receipt of a letter from a highly esteemed correspondent asking for further particulars in regard to this particular liquid. "I read an interesting article on the subject of lac, seed-lac, and shellac in THE BRITISH JOURNAL OF PHOTOGRAPHY the other day, and, as I have been looking for some information on this very point lately it occurred to me that I would write to the Editor about it. . . . Up to a few years ago we were able to make an exceedingly good lacquer for our brasswork, the colour was peculiar, and was much admired for our class of work. . . . The last few years, however, we have had great trouble with our lacquer; in the first place, the druggists refused to let us have the spirit unless there was something put into it, and we had to get the lacquer made up by the druggists. Now, however, we have got a licence from the Excise people, in order to get the spirit ourselves, and yet we cannot get the same class of lacquer we got in former years. . . . Some twelve or fifteen years ago I tried a great number of experiments about lacquer, and used all sorts of colouring materials, but I found that, although I could get almost any colour I liked with suitable dyes, these colours were liable to fade. . . . I finally got the very best result by using nothing but seed-lac . . . a beautiful lacquer, just the colour we wanted. . . . I have tried various specimens of seed-lac lately, and can get nothing like the old result," &c.

Before solving this riddle, which we think we shall do readily, we should like to refer a little more in detail to the varieties of lac found in commerce. It is a rather singular fact, in connexion with an article of such importance as lac, that the literature on the subject should be so sparse and the facts so variously stated. It is known to be associated with the life history of a little insect. The insect appears in vast

numbers on the small twigs and branches of certain trees; the insects die after depositing eggs, and the twigs are found covered with an incrustation variously stated to be the dead bodies of the female insects, a secretion exuded by them, or an exudation from the tree caused by punctures made by the insects. This we may leave to be settled by experts. The incrustation is there, and the twigs which they cover are collected. These twigs are termed "stick-lac." Seed-lac is the name given to the incrustations after being removed and triturated in a mortar, with the double object of dissolving the colour out of them (which colour is the basis of the famous lac dye) and reducing the little lumps to small pieces. Seed-lac forms the principal ingredient in many of the older recipes for lacquer at a time when methylated spirit had not been devised. Now, unless the natives have invented factitious seed-lac, it is quite evident that seed-lac at the present time cannot be any different from what it was fifty or a hundred years ago, so that any difficulty in making lacquer must be sought elsewhere.

Incidentally let us describe the production of shellac. The seed-lac is collected and placed in canvas bags, which are heated sometimes before a charcoal fire, and at others over a fire. When heated to melting the bags are twisted, and the lac drops out. If received into water it forms "button lac." When smeared, so to speak, over the smooth surface of a portion of the plantain tree it hardens and flakes off in the form of shell-lac. This shellac is of various degrees of translucency and colour. The finest is known as orange lac, and its quality is gauged by its glass-like transparency and the lightness of tint. The poorer qualities, as before described, are called "ruby," "garnet," &c., according to the depth of colour. "Lump-lac" is simply a melted agglutination of seed-lac. We have thus a complete key to the colour, and an explanation of the preference given to seed-lac. It is unaltered by the hand of man, and so possesses the virtues of gum-lac in the highest degree, and is accompanied by a portion of the original colouring matter, which is nothing but the well-known lac dye, one of the fastest of red dyes—the material used for dyeing the best quality of the soldiers' "red coats." The old lacquer makers preferred to modify and deepen this colour by adding various vegetable colours, notably gamboge, annato, saffron, and very frequently aloes. Many makers added sandarac or other gums to their lacquer to add to its brilliancy, though we are inclined to think that any addition whatever reduces its resistance to mechanical injury.

There is then only the solvent left to consider, and here we do not doubt the key to the mystery is to be found. Our correspondent is probably unaware that the methylated spirit of to-day is different from that of a dozen years ago. The new kind, as we have often stated, is made by adding a light petroleum oil to ordinary alcohol, the mixture being incorrectly termed "methylated." This name is only truly given to the old kind. The addition to the alcohol in that kind consisting of methyl alcohol, known also as wood spirit, wood naphtha, pyroacetic spirit, &c. If our correspondent will ask the Inland Revenue authorities to revise his licence and alter it to a permission to use the old kind of methylated spirit, we think all his difficulties will vanish. With regard to the solvents, there can be no doubt that something beyond a mere solution of the lac is needed, for it is well known that the users of French polish prefer either all wood naphtha, or at least a large proportion of naphtha in the liquid they use. Finally,

we append two very old and tried recipes for lacquers of different colours, which we know were in use more than half a century ago:—

Shellac.....	120 parts.
Sandarac .....	45 "
Mastic .....	30 "
Amber .....	30 "
Black resin .....	90 "
Dragon's blood .....	30 "
Turmeric .....	30 "
Gamboge .....	30 "
Rectified spirit .....	1000 "
Shake occasionally till dissolved and strain.	

Seed-lac .....	120 parts.
Gamboge .....	120 "
Dragon's blood .....	120 "
Saffron.....	30 "
Rectified spirit .....	1000 "
Put in a hot place, stir at intervals, and filter.	

**Celluloid Again.**—Evidently celluloid is not gaining in repute so far as safety is concerned. Last week a fire occurred at a celluloid factory in the Rue de la Folie, Méricourt, Paris, at which three firemen and one of the workmen were seriously injured and much damage was done to surrounding property. The extremely hot weather is said to be responsible for the fire. It is a little difficult, however, to see how the hot weather, hot as it has been in Paris, as everywhere else of late, could be the cause of the fire. Celluloid, as we all know, is exceedingly inflammable, but it wants a strong heat to ignite it, and it is not liable to spontaneous combustion, even when submitted for a long period to high atmospheric temperature. When accidents have happened with celluloid films at cinematograph exhibitions, the cause has generally been through a flame carelessly being allowed to come into contact with the film, or from its being permitted to remain too long exposed to the great heat of the condenser. We should say that, *per se*, the hot weather had nothing to do with this fire, and that celluloid should not be credited with it.

**The Observatory at Ben Nevis.**—Last week we referred to the closing of this Observatory because the Meteorological Council would not, out of its grant of between 15,000*l.* and 16,000*l.* a year, allow 500*l.* a year to keep it open, and the questions put in the House of Commons with regard to it. The question has since once more been raised in the House with reference to the way the sum granted to the Meteorological Council is expended and pointedly criticised. It was said that the Council took nearly 1000*l.* for managing the grant, while the Secretary also received 800*l.*; also that a sum was being annually set aside by the Council in order to provide for a superannuation fund which now amounted to 2000*l.* It was also stated that 3000*l.* had been sunk in the Ben Nevis Observatory, and that the benefit accruing to science from the expenditure of such money would be probably lost if the cycle of observations were not completed. Mr. Balfour, in reply, said that the Government have no information as to the details of the expenditure of the Meteorological Council except such as may be derived from its report. In reply to further questions by another Member, the First Lord of the Treasury said, "It is not for me to say whether the Meteorological Council does or does not carry out the functions intrusted to it to the best advantage." That may be so, but the public directly or indirectly have the right to know, particularly the scientific portion of it, as they are perhaps the most interested in the matter. An investigation into the grant to the Science and Art Department revealed something, and similar investigations in other departments might lead to good results.

**The National Portrait Gallery.**—During the past week several questions have been put in the House of Commons of more or less interest to our readers. One of them was with regard to three portraits that are for sale: portrait of the Queen in her robes of state, by Sir David Wilkie, R.A.; portrait of King Charles I.; and one of Queen Henrietta Maria, which may be had for the small sum of 3159*l.*, and which had been declared by the Trustees to be of great historical importance and their acquisition a great benefit to the nation. In reply to this, the Chancellor of the Exchequer said that he understood that the Trustees of the National Portrait Gallery do not now desire to purchase the portrait of Her Majesty the Queen referred to; and, as to the other pictures, he did not think there was a sufficient ground for a special grant for their purchase. Subsequently a question of similar import was put a few days later, and a somewhat similar reply given. It would seem, from the questions put and the replies given, that the Trustees of the National Gallery and those of the National Portrait Gallery are not quite working in unison, which is to be regretted.

By the way, why should a National Portrait Gallery be entirely confined to paintings, and then only if they are really works of art by the finest masters? One would have surmised that in a National Portrait Gallery portraits, good and characteristic likenesses, of distinguished individuals should be the chief consideration, whether strictly works of fine art or not. If this were the case, why should not photographs, by either of the two permanent processes, carbon and platinotype, find a place in it? Of many eminent men of national interest there are no paintings, by eminent or other artists in existence, or, if there are, their families would not part with them; but there may be excellent photographs of them. Why should not room be found for photographic portraits, say enlargements in carbon or platinum, from such photographs as are available? When one wishes to see portraits of eminent persons, they want likenesses of them rather than works of art by great masters, which, by the way, are not always good likenesses.

ANENT this subject, it is announced that the Queen has presented to the National Portrait Gallery a portrait of herself, in the robes worn at the Coronation, painted by Sir George Hayter, which is now in the Kensington Palace. This will certainly be an acquisition to the Gallery, though it is said that it is not possible to make arrangements for the immediate transfer of it from Kensington to Trafalgar-square.

**The Paris International Exhibition.**—In the votes in supply in the House of Commons, last week, was one of 60,000*l.* for the English section of the French Exhibition of 1900. This was passed without opposition or comment. It is to be hoped that photography, in all its branches, will be well represented. In previous international exhibitions in the gay city, English photography, in its multifarious phases, has not figured at its best, and it is desirable that it should next year, particularly when it is remembered that the most important discoveries and processes in connexion with photography must be credited to this country.

**The Vandyk Exhibition at Antwerp.**—In our last issue we referred to the Vandyk Exhibition, which opens on the 12th inst. to commemorate that famous artist's tercentenary, and the opportunity that tourists in Belgium will have for hand-camera work at the pageant through the streets prior to its opening. On a former occasion we have mentioned that Her Majesty the Queen owns, in her private collections at Buckingham Palace and at Windsor, some of the finest Vandyks in this country, which the public are made familiar with through the photographic reproductions of them by Continental photographers—Hanfstengl and Braun, for example. We now learn that Her Majesty has lent some of these fine works to the Antwerp Exhibition; amongst which are the half-length of

Charles I., from the Windsor collection; the famous picture (small whole-length) of the children of Charles I., the Duke of Devonshire (whole-length), and several others. Vandyk's work was almost entirely confined to portraiture, and it is well worth the study of portrait photographers—more especially the younger members of the profession.

# NIÉPCE AND DAGUERRE.

*The Bulletin della Società Fotografica Italiana* publishes a facsimile of the agreement entered into by Niépce and Daguerre. The following translation of this document may interest many of our readers:—

## BASIS OF PROVISIONAL AGREEMENT.

"The undersigned M. Joseph Nicéphore Niépce, landowner, residing at Chalon sur Saône, department of the Seine and Loire, of the one part, and M. Louis Jacques Mandé Daguerre, artist painter, Member of the Legion of Honour, and Manager of the Diorama, of the other part, hereby enter into the following provisional agreement for the purpose of founding a partnership:—

"Whereas M. Niépce has made certain studies for the purpose of recording the views of nature by a new method without the aid of a draughtsman, and various experiments constituting this discovery have been the result. The said discovery consists in the spontaneous reproduction of pictures formed in the camera obscura. And whereas M. Daguerre, to whom the discovery has been made known, perceiving its great interest and the great improvement of which it is capable, has offered to join M. Niépce for that purpose, and for securing all the benefits which may be derived from this new kind of industry: In view of these facts, the parties hereto have agreed to the following provisional and fundamental conditions of partnership:—

"1. A partnership shall be formed between MM. Niépce and Daguerre, under the commercial style of Niépce-Daguerre, for the joint purpose of perfecting the said discovery made by M. Niépce and improved by M. Daguerre.

"2. The partnership shall be for the term of ten years, dating from this fourteenth day of December, and prior to the expiration of that term shall only be dissolved by mutual consent. In case of decease of either of the partners, his heir shall succeed to the partnership for the remainder of the unexpired term of ten years. Further, in the event of the decease of either of the partners, the said discovery shall only be published under the joint name specified in clause 1.

"3. Upon signature of this agreement, M. Niépce shall disclose to M. Daguerre, under the seal of secrecy, which shall be so kept under penalty of all expenses, damages, and interest, the principle upon which the discovery depends, and shall furnish an exact and complete written statement of the nature, the working details, and the different modes of applying the processes connected therewith, in order that the experiments for perfecting and utilising the discovery may be carried out as completely and quickly as possible.

"4. M. Daguerre, under the same penalties, undertakes to preserve with the greatest secrecy the fundamental principle of the discovery, and the nature, the use, and application of the processes which shall be disclosed to him, and will co-operate, as far as possible, in the improvements which may be deemed necessary to the best of his abilities and talents.

"5. M. Niépce gives and cedes his invention to the partnership, as an asset, in consideration of half the profits which may be derived from it, and M. Daguerre contributes a newly designed camera, his talent, and his industry in consideration of the other half of the said profits.

"6. Upon signature of this agreement, M. Daguerre shall disclose to M. Niépce, under seal of secrecy, which shall be so kept under penalty of all expenses, damages, and interest, the principle upon which the improvement in his camera depends, and will furnish an exact written statement of the nature of the said improvement.

"7. MM. Niépce and Daguerre shall contribute in equal shares the capital which may be found requisite for the partnership.

"8. When the partners think it desirable to apply the said invention to the process of engraving, that is to say, when they have decided what advantages it may possess which would enable an engraver to make a trial plate, MM. Niépce and Daguerre hereby agree to select no one but M. Le Maître for carrying out the same.

"9. Upon execution of the final agreement, the partners shall mutually appoint a manager and a cashier of the firm, which shall be located in Paris. The Manager shall conduct the business as decided by the

partners, and the Cashier shall receive and make all payments as ordered by the manager in the interests of the firm.

"10. The Manager and Cashier shall be elected for the term of the present agreement, but shall be eligible for re-election. Their services shall be gratuitous, or a portion of the profits may be awarded them, as the partners may think fit, when the final agreement is made.

"11. The Cashier shall render an account to the Manager each month, showing the position of the firm, and every six months the partners shall divide the profits, as stated above.

"12. The Cashier's accounts, showing the position of affairs, shall be balanced, signed, and attested each half-year by both partners.

"13. The improvements which may be made concerning the discovery and the improvements in the camera shall be the property and for the benefit of both partners, and, when they have attained the object in view, they shall make a final agreement upon the basis of these presents.

"14. The net profits of the partners derived from the firm shall be shared equally between M. Niépce, as inventor, and M. Daguerre for his improvements.

"15. Any dispute which may arise between the partners concerning this agreement shall be decided by arbitrators appointed by each party privately, according to Article 51 of the Commercial Code, and their decision shall be binding, without appeal or revocation.

"16. If it should be decided to dissolve the partnership, the liquidation shall be undertaken privately by the Cashier, or by both partners together, or by a third party, to be appointed privately, or by some person appointed by a competent Court at the instance of the more active partner.

"The whole of this agreement has been entered into provisionally by both parties, who, for the execution of these presents, elect as domicile their respective residences, as specified above.

"Executed and signed in duplicate at Chalon sur Saône the fourteenth day of December, one thousand eight hundred and twenty-nine.

"Approved by me, though not written by my hand,

"J. N. NIÉPCE.

"Approved by me, though not written by my hand,

"DAGUERRE."

#### SIMULTANEOUS DEVELOPMENT AND FIXATION OF GELATINO-CHLORIDE PAPER.

HERR R. E. LIESegang points out 'in Camera Obscura' that if gelatino-chloride paper is faintly printed out under a negative, and be then placed in a bath which fixes it and at the same time develops it to full intensity, the only other operation would be the necessary washing afterwards. It is, moreover, not necessary to print to a given depth. The combined developing and fixing bath contains no gold salt; and, further, the bath is alkaline, so that sulphur toning is absolutely impossible. Although his experiments are not quite complete, he publishes the statement in order that others may try it.

In 1893, he had observed that a gelatino-bromide plate which was fixed immediately after exposure could be physically developed; \* for instance, with silver nitrate, hydroquinone, and sodium acetate. Experiments made at the time lead him to conclude that gelatino-chloride paper could also be simultaneously developed and fixed.

Some experiments, † in which fixation was attempted, not with hyposulphite of soda, but with the sulphocyanides, were without result; and even the addition of an alkaline dry-plate developer to the hypo bath caused no blackening of the exposed parts. The desired result he has now obtained by adding silver nitrate to the bath. But even a mixture of silver nitrate, hypo, and a developer such as is used for dry plates, worked only very slowly, the print had to be left in it at least the whole night. A developer which would give the print the necessary vigour in a short time was only formed when amidol and caustic potash was added to the solution of silver nitrate and hypo. The print first fixes in it, and then in about a quarter of an hour attains the necessary depth. The disadvantage that amidol, pyro, &c., lose considerably in developing power by the addition of a large quantity of hypo is very noticeable. The accelerating action which the addition of small quantities of hypo exerts in dry-plate development does not lead one to expect this. If amidol is mixed with an alkali, the red and blue oxidation products are very quickly formed. In the presence of hypo this does not take place; pyro even does not colour so quickly. It is even pos-

sible to decolourise a deep blue-coloured mixture of amidol and alkali by the addition of hypo. The bath used consists of—

Sodium hyposulphite .....	31 parts.
Water .....	150 "

This is mixed with—

Silver nitrate .....	3 parts.
Water .....	100 "

The precipitate first formed readily dissolves by shaking, and then there should be added—

Amidol .....	1 part.
Sodium sulphite .....	5 parts.

When solution is effected, add as much ten per cent. solution of caustic potash solution to make the solution slightly greenish; about twenty-five parts will be necessary. This bath is suitable for the development and intensification of dry plates.

#### FOREIGN NEWS AND NOTES.

**A New Anastigmat.**—M. Lacour, of Paris, has just completed a new lens, which he calls the anastigmatic eurygraph, which is composed of two symmetrical combinations, each being composed of three glasses, and perfectly corrected. The lenses are thicker at the sides than in the middle, thus recalling the concentric of Messrs. Ross & Co. The full aperture is about  $f/5.3$ , and at this aperture a lens of 14 l. cm. focus ( $=5\frac{1}{2}$  inches approximate) will cover sharply a plate of 11 x 15 cm. ( $=$  half-plate approximate). The single combinations will cover a  $7\frac{1}{2} \times 5$  inch plate at  $f/10$ .

**Silver Stains.**—Herr Weiss, of Vienna, states that, if a negative which has become silver-stained by contact printing with silver paper be immersed in a solution of yellow [? red.—Ed.] prussiate of potash, and then treated with a hydroquinone developer, they will be totally removed, and the negative not be reduced in density.

**A Simple Sensitiser.**—M. Niewenglowski suggests the following method of preparing a one-solution sensitiser, which may be applied to almost any material without any preliminary preparation if it be fairly well sized:—

Distilled water .....	10 parts.
Silver nitrate .....	3 "
Uranium nitrate .....	30 "
Absolute alcohol to .....	100 "

Apply the solution with a brush, allow to dry in the dark, which takes about ten minutes. Expose in contact with the negative, and fix by immersion in two or three baths of water acidulated with nitric acid, and then rinse in plain water and dry. It is advisable, if very rich tones are required, to dry in front of the fire or iron with a hot flat iron.

**Intensifying Collodion Negatives.**—M. Fery suggests the use of cupric bromide, followed by silver nitrate, and then by a hydroquinone developer, for intensifying collodion negatives. The negative, which should be thoroughly washed, is to be immersed in a solution of—

Cupric sulphate .....	25 parts,
Potassium bromide .....	25 "
Water .....	1000 "

till bleached. The action of this is the formation of cuprous and silver bromide:

After washing, the negative should be immersed in a two per cent. solution of silver nitrate, when the following action takes place:—

The silver bromide formed in the first bath remains unaltered, but the cuprous bromide forms more silver bromide. The plate should then be washed and treated with the following:—

Hydroquinone .....	10 parts.
Sodium sulphite .....	75 "
" carbonate .....	150 "
Water .....	1000 "

This reduces the silver bromide to the metallic state, and gives a density twenty-seven times greater than the original without blocking up any of the fine details.

\* Photo Archiv (1893), p. 67.

† Photo Archiv (1893), p. 28.

**Another Snap-shot.**—The following storyette appears in one of our foreign contemporaries, and it may or may not be true. An artist's model was standing at the corner of one of the streets in Paris, waiting for some of her companions, and "fourra nerveusement l'index de la main droite dans le nez," when she espied an amateur taking snap-shots of her from the second-floor window of an opposite house, and, disgusted at being taken at such a moment, she loudly upbraided the inconsiderate camerist, and the two were promptly hauled before the inspector of police of the quarter, when the grisette explained that, as she was an artist's model for heads, and received 10 francs per sitting, she strongly objected to be photographed without her express permission. The amateur pleaded that he was merely taking a snap-shot of the corner of the street, but gallantly opened his camera, allowed the sensitive model to smash the sensitive plates, and she departed satisfied to her work.

**Dr. Vogel's Successor.**—Dr. Adolph Miethe, the well-known photographic writer and expert, has accepted the appointment of the professorial chair rendered vacant by the death of Dr. H. W. Vogel, at the Technische Hochschule, Charlottenburg, Berlin.

**Artistic Results.**—Ritter von Schöller, of Vienna, states that he has obtained excellent results by using Liesegang's old iodine paper, which can be very easily prepared as follows: Into a solution of—

Potassium iodide .....	10 grammes,
Potassium chloride .....	40 "
Water .....	1000 c. c.
Lemon juice .....	250 drops,

are placed 20 grammes of tapioca which have been allowed to soak in cold water for one hour, and the excess of water poured off. The mixture is now heated to boiling, and well stirred until the solution becomes quite clear, and it is then allowed to cool, and then paper of the desired surface is coated with this by means of a brush or swab of cotton-wool, and allowed to dry. The paper in this condition will keep for any length of time. To sensitise this, it should be floated or painted over with a solution of—

Silver nitrate .....	60-100 grammes.
Citric acid .....	5 "
Water .....	1000 c. c.

The more silver used the more brilliant the prints. The paper, when dry, is exposed till the details are distinctly visible, and the print is then placed in a developer of—

Gallic acid solution (saturated) .....	1 part,
Water .....	4 parts,

till the desired vigour has been obtained, when it should be well rinsed, and fixed in a ten per cent. solution of hypo. Charming black and brownish tones are thus obtained.

## RETOUCHING.

[Paper read before the Royal Photographic Society.]

THERE are many who cannot or will not recognise the legitimacy of this art in its association with the science of photography. I can scarcely think this fair, as, however much amateur photography may be independent of retouching, professional portrait photography is commercially very much dependent upon it for success. I do not wish to insist upon retouching being the chief point, but I do insist that it is an essential one, in the production of successful portraiture. The retoucher should work in closest sympathy with the operator, and help him to carry out the artistic notion to which he first gives existence in the shape of a negative. The retoucher necessarily comes second, as the negative in the first instance must be the operator's production. I consider retouching a natural offspring of the simple process of development, for it is in a manner a process which enables the operator to accomplish the very difficult task of intensifying the negative in certain minute parts where intensification is necessary—an operation which would be quite impossible by ordinary chemical treatment in the usual way. The process first adopted for carrying out retouching was a very rough-and-ready one. The operator in most cases usually worked out the blemishes with water colour, some manipulators using one tint and some another.

The very earliest colour used for this purpose was, I believe, blue; then followed neutral tint, Payne's grey, and kindred tints, until finally the lead pencil took a firm hold, to the complete exclusion of all other means. Its working was easier and more convenient, to say nothing of its greater reliability, the actinic properties of the deposit being more easily and justly appreciable than those of any vehicle employed in any of the other methods formerly in use.

Retouching was first introduced in the old wet-plate days, and, to a few of the more advanced and up-to-date workers in photography about the middle of the century, proved the means by which big positions in the profession were secured, as well as enabling them to considerably inflate their banking accounts. In those days it was the custom to stipple out the blemishes with blue or neutral tint, as I have already stated, and thus to build up the defective parts of the image so as to produce a more pleasing picture than would otherwise be obtainable from the untouched negative. Of course, there was but small scope for variety of method or treatment in the working of this style, as the most natural and easy means of applying a flowing colour to a plate so highly sensitive to moisture would be to stipple the same on with a moderately dry brush. With the adoption of the lead pencil for retouching, however, all this was very much altered. There was imparted a greater variety of possibilities, to be limited ultimately only by the artistic feeling of the artist carrying out the work. This limitation, I am sorry to say, is but very ill-defined, and seems to be shifted about in the most reckless manner to suit the temperament of the artist, or of the photographer by whom he is employed, or the whim of the customer. It is much to be desired that a definite limitation should be fixed, and a positive theory adopted from this standpoint as to what good retouching really means.

I regret that there seems to be such a divided opinion as to what is and what is not the correct way to carry out this interesting work, as also to what extent that work may sensibly and artistically be carried. As I say, limitation is but very ill-defined, and to add to the general confusion the various writers on the subject have laid down divers and contradictory methods as being the only correct ones to be used in the working. The "cross-hatch," the "dot and tail," and the system of touches resembling the letter "S," are all set down as the best or only stroke or touch which can produce artistic retouching. These touches are all very good and nice in their way, and will give very charming and pretty effects; but I cannot see that the results are quite artistic, nor are they at all natural or calculated to produce sound portraiture. I have always held that retouching is not such a poor art as to be run on such narrow lines; and I have always endeavoured to uphold that there should be no such thing as a regulation touch, but that, on the contrary, there should be perfect freedom in the use of the pencil in taking out or modifying a blemish or altering an expression. I always desire to believe that there is more virtue in the intention of the artist than in any peculiar mean she may use to express it. Such touches may be very well now and again, when they suit the blemishes, but I think it a folly to lay down a regulation touch as the sole and only manner in which artistic work should be carried out unless they order the blemishes, &c., to be made to suit them. If portrait painters adopted such a method as this, what a fine show our National Portrait Gallery would present (?) We, however humbly, should follow the example of our betters, even if at a very respectful distance—it will always do us good. I fail to see that any artistic feeling is possible in "regulation" work, except it be accidental, but assuredly there is no common sense. I would submit this point for your consideration. If a blemish be of some particular shape, why should we cover it with a tissue of marks of a different shape? The shape and quality of a touch should be entirely governed by the shape and quality of the blemish; neither should our touch, however free from mannerism, be too positive and defined, as this will tend to destroy the quality of the skin (as is the case in the mechanical touches before referred to), and I may say that in my humble opinion the skin is a very important factor in any portrait. Regulation touches will give you what is called texture, or grain, but they will not give skin; and the point to be considered is, Do we prefer texture, or do we prefer skin? In the prevailing methods of working negatives little attention, if any, is paid to this matter—no thought, no brains. All heads are touched in the same way; strong men, weak men, old ladies and young ones, and even children, are all treated alike—there is only one skin on top and all must have it, be it natural or not. Now, this system of smoothing—for it is nothing else—is so generally adopted that there is no very distinctive difference between the work turned out by our first-class London houses, at enormous prices, and the moderate-priced work of our falsely designated "second-rate" country photographers. Is it wise that this should be so?

Let us examine this smoothing-up process for a moment, and see what a foolish thing it really is. Delicate detail, fine modelling, artistic light and shade, are all difficult qualities for the operator to secure, and yet the retoucher is allowed to quietly sweep them away, and for what purpose? simply to gain that polished surface which is so dear to him, and which with so many passes as the acme of good retouching. See if there be any life in the faces; are they not cold, hard, and in most instances expressionless and uninteresting? I think, however, you will find that there are many who yet consider them very good work, notwithstanding the fact that nothing short of a most impressionable imagination will be able to trace in them the least resemblance to the

originals. Of course, we can always assure ourselves that it is a certain portrait by examining the watch-chain, the neck-tie, or some other article by which the identity can be established and so the face can be done without. But is this as it should be? I think it may safely be said that ladies are more susceptible to undue flattery than are men. That being conceded, it is only fair to say that when men are open to flattery they will go a considerable distance to secure a record; in fact, I know examples that would make us all blush for our sex. In my own experience the complete alteration of a nose is but an ordinary affair, but I have also had to improve the symmetry of a gentleman's back, when increasing weight and years had somewhat marred his former beauty. But we will pass these over as the exceptions that prove how sensible we ourselves would be. What we ought really to consider is, Should we not be more judicious in our flattery, and use greater skill and thought in carrying it out? I feel sure that, if a better standard of opinion were established on this point, an all-round good would result, alike to the retoucher, the photographer, and the general public. One would not so often see, and hear it said (unfortunately with a very large degree of justice) that the best likeness of Mr. or Mrs. So-and-So was taken by an amateur friend, in his back garden, the only apparent reason being that, although the portrait is much worse from a purely photographic point than those taken by professionals, it has not been retouched. Examples of this kind crop up almost daily; I find very often that, when a death occurs, in nine out of ten cases amateur photographs are sent to me for copying or enlargement in preference to the ordinary studio picture, on the ground that "it is such a good likeness," although the negative is in all other respects a very bad one. Experience—and I have had a fair share of it—has always been full of object lessons, and I have always tried to gain instruction from them as I have struggled along, and I am just as open and willing to learn some point this evening as I was twenty-five or more years ago. Believe me, we should all live and learn, and I hope it may be long before any of us cease to do either. The moment we cease to learn and hope to improve, retrogression sets in, and we may rest assured that conceit, that most objectionable of qualities, will soon take firm hold of the victim, and ruin his or her future.

If my objections to the fallacy of regulation methods of retouching, as popularly laid down, be true as regards their application to professional portraiture, how much more so must they be when applied to amateur work and to other branches of the art science? Amateur work, taken under all conditions of light and in the face of many difficulties, should never be treated by the retoucher as within the same narrow limits which may be more or less sufficient for professional studio work, a fact which I have no doubt you have all observed.

How much more truly must all this apply when we attack the other branches of photography, such as landscape and architectural work. Retouching can be very largely employed in these interesting branches, and here again the healthy and untrammelled use of one's brains comes in with even greater advantage. To remove blemishes is but an item in the work we do; often it is possible to add an effect of light or shade which is not in the negative, or to emphasise an effect which, although indicated, is not powerful enough to assert itself. It is only during the past few years that I have been called upon to treat architectural and such kindred subjects. At first I scarcely knew what to do with them, unless I found an unhealthy lot of blemishes staring me in the face, but I at once reflected and realised that the subject was well worth studying up. I therefore started buying engravings, of which I have now many hundreds, and from them learned how to make a picture of interest of a photograph almost devoid of beauty, with ample technical detail but no artistic balance of light and shade. With engravings before one, taken from the best point of view, inside or out, of the various edifices noted for their beauty and grandeur, one can find ample food for reflection and a chance for some good work. The originals of these engravings were not only sketched from the best points of view, but they were finished by such giants in the handling of light and shade as William Henry Bartlett, Allom, Roberts, and Prout, and they are invested with all the beauties of that artistic balance of which these artists were such rare masters. The photographs one has to treat may probably have been taken from the same, or nearly the same, standpoint, but how about the artistic effect of light and shade? The enthusiastic and artistic photographer must have full credit both for knowledge and artistic feeling, but, be these qualities ever so great, he cannot command the light to his wishes and can only take the view as the light will let him. This is no fault of his, for, struggle as he may, he cannot get what he originally hoped for, and must be content with whatever image he may secure on his plate. Now is the time when we as retouchers can second his efforts and help him to procure those effects which he had hoped for but found impossible to secure. By washes of colour, papering the back of the negative, stumping in lights, &c., we help him to secure a success. This should really be considered as part of our art, and the student should pursue it still further for instruction, as I do, by making a study or a hobby of restoring engravings and mezzotints. I promise you, you will find such work most enjoyable, as well as instructive. Working in this way, one naturally trains the eye until one acquires a most sensitive feeling for artistic beauty which will be invaluable to us, to say nothing whatever of the attendant pleasures of the occupation.

I have often wondered why amateurs, and especially ladies, of artistic

taste, have not gone in for retouching more seriously than they have done. I cannot think that it is owing to the little difficulties which beset the path of the beginner. No, I think it is more traceable to the fact that the teachings on this interesting subject are such as to shut out the artistic opportunities which alone would induce the better class of amateurs to undertake the trouble of learning. I know cases of ladies who have so-called beautiful photographs, and who have yet declared that they had not a likeness of themselves which they would leave to their family. There is a lot of money waiting for the amateur or professional photographer who would supply this want—a good photograph and a good likeness. Another question worth pondering over is, Can a bad likeness be looked upon as a good photograph? A discussion on this point might result in a real benefit to our photographic portraiture as represented by the photography of the day.

At the conclusion of his paper, Mr. Barrett invited the members present to submit prints to him for friendly criticism, with a view to some understanding being arrived at upon the question as to what is good retouching, but, there being no response, he continued:

Let us take as examples the portraits of the fathers of photography, upon the walls of this room. The majority of them were, no doubt, taken in the days of more or less untouched negatives, but I do not think the Society would care to have them replaced by photographs in the present style. Surely a medium between present-day work and the old style would be a much safer line to work upon than the one plan of continual smoothing. Some years ago I saw a 15 x 12 group of a lady and gentleman and a child, taken by a leading photographer, all the faces having the same touch; I did not consider that good—certainly it was not thoughtful, for there should have been differences in the texture of all three. I have found that the negative itself holds a certain impression of the real skin; i.e., that there is the texture of real skin in the negative if we in retouching do not make our touches so vivid and aggressive as to destroy it. I can retouch a good many large heads in a day, but I could not do so if I did not make use of the negative itself; and where the negative prints fairly white I do not encumber it with much retouching. I think, too, that in retouching a great deal of attention should be given to the improvement of expression. It very frequently happens that a sitter gets an unfortunate expression quite unlike that which is natural to him, but the slightest possible amount of work on the negative is sufficient to remove it and to produce a pleasant and natural likeness, and it can be done by any one who will take the trouble to think. The people who learn retouching are not sufficiently taught the importance of training themselves to think; they are taught to do, but there is really very little to do—most of it is *thinking*—thinking how very little pencil will make a successful picture.

The President agreed that the great objection to modern retouching arose from the fact that so little thought was devoted to the work. In using a wax head for making experiments in lighting he got something approximating to the appearance of the highly retouched portraits exposed for sale in shop window, a result quite unlike skin and devoid of expression. Another cause of the unsatisfactory nature of retouched photographs was that the retoucher gave his idea of what the face ought to be rather than what it actually was, and this was almost unavoidable unless he had an opportunity of studying the original.

Mr. Barrett continued, answering one or two questions which were interjected in the course of his remarks. The beauty of every head consists in its expression, and more success is gained by attention to that detail than by working up what is called a beautiful finish. I think ladies would be much better pleased with their photographs if their expression were properly rendered—with, perhaps, a reasonable amount of flattery—than with portraits in which everything is carefully smoothed out for the sake of "finish." Youth can be partially restored without burlesquing the original; there are certain faces that will admit of flattery without losing the likeness, but there are others which will not stand it without becoming grotesque and unpleasant to those who know the sitter. The medium which should be aimed at is the point which will produce a successful portrait and at the same time a pleasing likeness; it can only be arrived at by limiting the amount of work as much as possible, for the more pencil you put on the negative the more likely are you to lose the likeness. The degree of hardness of the pencil employed depends largely upon the peculiar touch of the user; personally I prefer No. 3 lead, a very safe pencil with which almost anything can be done. With a hard pencil there is a tendency to increase the quantity of work, and consequently to overdo it. With a No. 4 it will perhaps be necessary to make two strokes to produce the effect of one stroke with No. 3, and with No. 5 three or four strokes may be required, and that is dangerous; but one delicate touch with No. 3 will give the full amount of deposit and obviate the risk of over-working. A good method is always to take out the major blemishes first. It will be found that the blemishes occur, as it were, in series or rows; take out the glaring ones first, and then the second row will appear to be pretty bad—take those out next, and you will find that very little remains to be done. Do not continue touching and touching the negative until it will take no more lead, but be satisfied when the blemishes are gone. If the negative is to be printed on a high-surfaced paper, the touch should be finer and softer than when platinum prints are required; I can retouch a large head for artistic effect in platinum printing in a very short space of time, but quite double would be

necessary for silver printing. Freckles present no difficulties and may be looked upon as the front row of blemishes, and as a guide for the rest of the work. The object in removing a blemish should be to destroy its shape, not to fill it up, which is ruinous to the photograph, because by filling it up you produce white and thereby loss of colour, a quality most essential to a good picture. Where the pencil touches the negative for the first time the deposit should be greatest, and from that point to the finish of the touch, it should become lighter, so that the end of the touch is simply the little bit that knits the work together. The severity of the expression of a man's face can always be softened, but the retoucher need not go so far as to put a laugh on the face of a man who never smiles. Ability and beauty do not always go together, and the retoucher should not take the brains out of a man of great ability, leaving him nothing to show his claims to be above the average. Where a man is the possessor of considerable ability there are always indications of it in his face; yet he may have no pretensions whatever to beauty. Now, in trying to make such a man beautiful or even good looking, we will surely deprive him of his undoubted ability, and fail in producing a good portrait. The late Mr. Gladstone was an example of what I mean; what would his portrait be without the wrinkles? Half the people who learn retouching are not taught to think; I invariably make my pupils think for the first six lessons, and then they can almost do for themselves. There never has been a portrait negative so perfect that a small amount of retouching will not improve it, and the great object should be to know when to leave off; nature has colour to help her, but photography has only black and white, and, if a line is too harsh or too cold, a very small amount of modification, as in the lines under the eyes, will often be of material assistance in reproducing the effect of nature upon the eye of the observer. The necessity for retouching arises primarily from the fact that the colour of the skin is made up of minute particles of different colours so blended that to our eyes they appear to be one colour natural to the skin, but in the photograph there is a differentiation between them which it is necessary to some extent to remove. The removal is done by means of retouching to the necessary extent, and that is not very far. A mistake is often made in retouching the shadow side of a face, making it appear full, perhaps while the lighted side is thin and sunken; it should be remembered that the slightest touch on the shadow side has twice the importance it would have on the other side, and that all the well-indicated features should be kept. For publication work over-retouching is more acceptable, because people buy photographs of actresses and professional beauties simply because they are pretty, and not because they are good likenesses; but with well-known public men and men of learning and intellect flattery is ruinous, because we really want likenesses of them and do not care whether the portraits are pretty or not. The question of retouching landscape and architectural photographs brings in some different considerations; I think the printing in of a sky or a foreground is quite justifiable, but here again there is not sufficient thought exercised. How often do we see a sky that does not approximate to the effect of the water in the foreground, or that does not coincide with the lighting of the landscape. But there are frequently points in a landscape where a deepened shadow would add a value or where the infusion of transparency would materially benefit the picture. This sort of work cannot be so well done by the pencil as by a stump of a brush, for the touch of a pencil is antagonistic to somewhat broad effects, and it must therefore be accomplished by washes of colour, or by paping the back and using the stump where required. The same remarks apply generally to architectural work, where the deepening of a shadow often relieves the rest of the picture and more perfectly renders the idea of distance. I do not think that the insertion of a line of a beam in a roof, for instance, would catch the eye more than would be the case if the actual beam had been photographed, providing the work was properly done; and I think it would be justifiable to give the effect of a ray of sunlight coming through a window, or any other natural effect, that could have been secured in the negative by patient waiting or under certain conditions. In architectural work, as in landscape, breadth of light and shade is the object in view, and therefore a wash of colour is more satisfactory than the pencil, which is better adapted to the rendering of minute detail.

Mr. Snowden Ward, referring to the value of retouching on architectural subjects, said he believed it was an open secret that some of the wonderfully fine interiors shown at recent exhibitions of the Society were from negatives which were first covered with papier minéral, which was then cut away from the places where it was necessary to emphasise the shadows and coloured with a crayon and stump where it was desired to lighten any portion.

Mr. Barrett: I do not see that there is any illegitimacy in working on the back of a negative in order to secure effects which the operator would probably have obtained by means of the camera if it had been possible, but it would be a distinct advantage if some authoritative pronouncement were made upon this and kindred subjects. A negative often contains a great deal of distinct but unprintable detail, and one is in my opinion quite justified in adopting any means for the purpose of bringing it out properly in the print. When one comes to the question of adding some feature which was not present in the original, one is on more debatable ground; but, even if it be a sin, it is a very small sin if by it an artistic and beautiful result is obtained.

REDMOND BARRETT.

## COLLODIO-CHLORIDE VERSUS GELATINO-CHLORIDE.

It is peculiar that for glossy or enamel papers gelatino-chloride takes the lead, says Mr. G. Hamner Croughton, in the *St. Louis and Canadian Photographer*, but for matt papers there is practically but one paper that has any large sale, and that is a collodion paper. The reason for this is hard to discover, for the advantages and disadvantages of both papers, when weighed one against the other, is to my mind decidedly in favour of the gelatine matt. First I will take the question of surface. A collodion print is much more easily damaged after it is finished than a gelatine print. I have seen some collodion prints that were scratched by simply pushing them into the envelope. You cannot damage matt gelatine print in that way—in fact, you may rub your hardest with an ordinary handkerchief, and they will show no mark. The tenderness of surface makes a collodion print more difficult to handle in washing, toning and fixing, &c.—a very important item where a large number of prints have to be handled.

Again, a collodion surface is much more susceptible to stains from finger marks, &c., than the gelatine, so that much greater care in handling is required.

There is another aspect of this question which the advocates of collodion either do not know or they carefully ignore, viz., that a collodion paper is much less rich in the silver salts than gelatine, for, while there is no limit (within reason) to the amount of silver you can put into a gelatine emulsion, there is a decided limit to the amount of silver you can get into a given amount of collodion. As a rule, it can be safely said that the best gelatine paper upon the market has at least one-third more silver to the ounce of emulsion than the collodion papers have. Any practical printer will appreciate the importance of this fact.

A recent correspondent of the *St. Louis and Canadian Photographer*, writing in favour of collodion paper, mentions the fact that Mr. Bruce, of Duns, Scotland, used collodion paper over a quarter of a century ago, and continued to use it, but he forgets one important fact, viz., that collodio-chloride paper was the only emulsion paper made in those days, and that after the advent of gelatino-chloride it went into disuse, except in one or two instances.

I was well acquainted with Mr. Bruce, and was using collodio-chloride paper at the same time, and he and I exchanged experiences with regard to it, but I gave up using it as soon as a reliable ready-sensitised albumen paper was put upon the market.

There is another fact that the writer does not take into consideration, and that is that the Obernetter paper was put upon the market at a time when single albumenised paper was used, and therefore we were satisfied with a great deal less of the patent leather shine than has been demanded since. It was years before the era of baryta-filled papers, and that means a great deal to the manufacturer of collodio-chloride papers. Any manufacturer, or any one else, who has had any experience with the present-day baryta-filled papers, knows to his cost that with collodion emulsion he is much more dependent upon his paper stock for his results than the manufacturer of gelatino-chloride papers. The same emulsion on different papers will yield entirely different results.

Mr. Bruce and I both coated our own papers as well as using that made by Obernetter. We coated the Rives or Saxe papers sold for albumenising, and never failed to get good results upon it, which is more than I can say of later experiments upon various filled papers with the same formula. But the present-day photographer would not be satisfied with the modest gloss obtained with collodio-chloride upon an unfilled paper. Hence the manufacturer had to supply a paper so filled that the emulsion rests upon a substratum of various kinds, instead of on the pure paper itself.

To sum up, then, I have failed to find any warrant for the statement that a collodio-chloride print is more permanent than one made on gelatino-chloride, and, unless the advocates of collodio-chloride can prove that it is, they must give up the case, as there are so many advantages in handling and manipulation that, granted the claim of permanency or stability being equal, the gelatino-chloride paper must be awarded the palm.

I do not profess to be a prophet, but there is one thing I will venture to assert, viz., that the recent agitation with regard to the permanency of emulsion papers will not tend, as some think, to a return to albumenised paper. That would be a step backward indeed. The result will more probably be to call the attention of photographers to other methods of photographic printing, where the filled papers are not used and the toning process is dispensed with. This is found in the platinum process and the various other developing papers upon the market.

An old friend in England, in a recent letter, called my attention to the fact that he demonstrated before the South London Photographic Society a developing paper some twenty-five years ago or more, and adds that it is his opinion that there lies the printing process of the future. I believe he is right. There is everything to recommend it. There is no doubt of the stability of a developed print. The emulsion is coated upon a pure paper, without the baryta or other developed substratum. The colour is a pure engraving black, with the light formed by the pure paper itself. We are coming back to first principles, and it will not be long before the filled paper will be a thing of the past, and photographs will not suffer in stability thereby.

## PRACTICAL HINTS ABOUT PHOTOGRAPHY AT THE SEASIDE.

The following extremely useful article appears in *Photographic Scraps* for August: Those of us who can only get one holiday in the year, naturally wish to make the most of it by combining sea-breezes, summer days, and the use of our camera; but, having spent eleven months of the year away from the seaside, we hardly realise the special conditions for turning out the best work under somewhat novel conditions. Consequently, on development of our exposures, some disappointments and failures are found. It is with the intention of pointing out some of the more likely ways and directions of making mistakes that these seaside notes are put together. It may be found convenient to group our hints under a few different headings.

**Light and exposure.**—Most photographers know, in a more or less general sort of way—that is, they have “heard it said”—that the light at the seaside is quicker than it is inland; but comparatively few at all adequately realise *when* this is especially the case, and *why* it should be so. First, we must remember that the air at the seaside is usually clearer, i.e., clearer than in towns, there is less dust, smoke, and fine floating particles. Consequently *direct sunlight* is somewhat stronger, and we know this by the almost painful glare when the “sun is on the water,” i.e., when the rays which fall on the water are reflected or thrown back into our eyes. This explains how it is that the shadows of objects at the seaside look so much darker than usual. As a matter of fact, it is not the shadows that are darker, but it is the direct light, which is so much stronger and brighter, which makes the shadows appear by comparison to be darker, for a cast shadow is not a positive existent thing, it is the *absence* of light. This is a point of some practical importance, which we must bear in mind when considering what exposure we shall give to this or that subject. The tendency is for the eye to be deceived by the extra bright direct strong sunlight, and to ignore the old rule of “Expose for the shadows, and let the high lights take care of themselves.” Hence, so many snap-shots which yield prints of the “soot and whitewash” description. These usually indicate a twofold fault on the part of their producers. First, they are under-exposed; secondly, development has been too prolonged, in the vain hope that a longer time in the developer will compensate for too short exposure.

Next, with regard to reflected light. And here is the stumbling block for the beginner; for, when we tell him to give a shorter exposure on a cloudy day than on a cloudless one, he is apt to think that is “chaff,” and not practical advice.

However, this can easily be shown to be sound advice. Let us suppose the accompanying diagram to show us the relative positions (but not relative sizes) of a bit of sea, with cliff along shore, a church in a valley a mile or two inland, and a bank of cumulus cloud overhead. We are supposing the sun to be over the water, so that direct sunlight falls in the direction *s w*, meeting the surface of the water at *w*. Now, every one knows from experience how the surface of water or wet mud, rocks, sand, &c., acts like a mirror and reflects the light. Thus, the sunlight coming from direction *s* is reflected at *w*, in the direction *w c*. At *c* it is thrown upon a bank of cloud, and here it is scattered, i.e., thrown back in various directions such as *c x*, *c y*, *c z*.

Thus the cloud becomes a large source of light; in fact, a large number of very small suns spread out over a space equivalent to the size of the cloud, and these tiny suns (or water drops composing the cloud) send light in all directions. And so it comes about that, while the sea itself may not be visible from the church in the valley, yet it is bathed in a flood of light, which is thrown upon it by reflection from the sea.

Now let us suppose for a moment that the cloud bank, *c*, is removed, then the light reflected along *s w*, and then *w c*, passes away overhead, and, so far as this valley is concerned, it is lost. Thus we can see that we get more light on the church with clouds overhead than when the sky is cloudless. Observe also that this effect is not limited to a few hundred yards away from high-water mark, but may, with sun and clouds in favourable position, apply to places ten miles inland. If the beginner will keep this rough diagram in mind, he will find it help him in considering whether the clouds overhead are likely to be throwing down light reflected from the water.

And now let us again turn to the practical application so far as it affects our exposures. A moment's quiet thought will show us that with the cloud, *c*, overhead we shall have light scattered, more or less, in all directions, and consequently the shaded, or less lighted, side of our subject will have some extra light; in fact, it will be much better lighted than if the sun were overhead and strong light falling upon it; that is to say, with scattered light from the cloud our shadows are lighter than

with direct sunlight. Hence, recalling the old rule about exposing for the shadows, we see why our exposures will thus be shortened when our subject is lit by reflected cloud light.

It goes almost without saying that any large expanse of water, e.g., a river or a lake, will act just like the sea, i.e., as a vast reflector.

**Selection of subject.**—On this point a great deal more might be said than we can here find room for. We must therefore confine our hints to one or two of the more common mistakes or oversights which the less experienced are apt to make. One common cause of failure is that of misjudging *size* and *distance* over water. For instance, we see a full-rigged ship with all sails out away at sea. We know it is a fine vessel of considerable size, so we take a snap-shot with the hand camera; but on developing the plate, we are woefully disappointed to find that the tops of some railings, which we had not noticed, come out of great size, whereas our stately vessel appears a mere speck; with difficulty we just see the masts and sails, but the whole thing is a miniature, almost microscopic, when compared with what we thought we saw and what we expected.

Of course, if you are using a camera with focussing screen, you are not so liable to make mistakes of this kind, for you can see beforehand the proportions of your picture; but, if you are working with an ordinary hand camera, here is a little tip that will greatly help you to realise relative sizes, and foresee how large objects are likely to come out on your negative.

Take three ordinary stout pins with rather large heads. Cut them down so as to leave the head and about one quarter of an inch of pin. Now find the exact centre of the top of the back edge of your camera. This point will be just over the middle of a plate when placed ready for exposure. Here drive in one pin, so that its head may easily be seen. Next, draw an imaginary line across the top of your camera, so that it comes just over the diaphragm slot of your lens, or as near as you can get to that position; then drive in the two other pins, one to the right, the other to the left, so that they are as far apart as the length of your picture, or say, for a quarter-plate, four inches apart. If, now, you hold up your camera with the top level with your eye and your eye just behind the back pin, you can at the same time see the two front pins (four inches apart) and any distant object. This will enable you to compare the size of any object with the length of your plate. A very little practice with this simple dodge will enable you to spare yourself many a disappointment as regards the size of distant object, for it is a matter of common knowledge that it requires practice to judge distances over water. Closely connected with this topic is that of judging the angle of view; for, our judgment being upset by under-estimating distances, the result often is that we find we have included a very much greater range of view than we anticipated. Here, again, we find our three pin heads come in helpfully for they at once show how much view our plate will include; in fact, they give to us a simple but useful form of view-meter.

Our next hint is one drawn from the inspection of a considerable number of seaside snap-shots. In a word, it is the fault of including too many objects of interest in the view, with the inevitable result that the eye is confused, and the print is put aside, as irritating rather than pleasing. This goes to show the truth of the well-worn quotation, “The most important part of composition is omission.” Here is an excellent bit of photographic work, almost faultless technique, but in the space of a quarter-plate print we have, in the foreground, a man painting a boat, an admirable figure caught at a very happy moment—just beyond, a group of fishermen, hauling up another boat—beyond them, several other figures—still further away, a group of boat huts—beyond that, a ruined building on a cliff—and, behind all, an attractive sky. Here is material enough for, at least, four different pictures, but, when all put together, it is a case of “Prince, this is too much.” If your aim is not only making negatives, but also making pictures, do not forget that there is nothing which gives to a picture the strength that comes from extreme simplicity of subject.

We all need this reminder when at the seaside, because there are usually so many picturesque objects about us in all directions that our danger is not so much that of getting faulty subjects, but of having in the same picture too many different objects which have little or nothing to do with each other, and therefore are not helping each other, but are all calling out for our attention.

## MENTAL AND MORAL TRAINING IN PHOTOGRAPHY.

[From the Photo Era.]

I HAVE noted the importance to photography of manual training in the art of drawing. In acquiring a mastery of the hand we develop the mental organs that govern the sight. We have seen that the practice of drawing from nature will increase the judgment for selection, and the judgment of the ultimate result. In this paper we shall consider the effect of mental and religious culture on the development of photographic art.

As with the sister arts, the production of photography will respond to the condition of the mind. If it is elevated by high culture, the character of the work will harmonise with it. Here lies the importance of a general recognition of photography as an art. The cultured mind will see a legitimate field for the exercise of aesthetic judgment,

Those who fail to recognise photography as a fine art view it in its mechanical process, with no consideration of the mental force that is at the foundation of this branch. There may be little effort of the mind in the crude photograph (crude painting must come under the same ban); but, as the work of production is imbued with thought, the results are artistic, till finally the æsthetic expression is so great that a painting must be of high grade of art to equal it.

An eminent example of elevating thought in photography is seen in the collection of F. Holland Day. Not only in his remarkable heads of Jesus, but in his figures and secular heads, is the confirmation of the statement that the rendering of nature by any method in which the result is responsive to æsthetic thought is art; and, as the thought is ennobling, so is the art. Mr. Day is not a man to theorise around a vital subject, but he goes directly to it with concentration. Words are not necessary to assure the beholder that his productions are works of art.

Appointed as one of the Judges at the Exhibition of the Brooklyn Camera Club, the writer had the privilege of studying works of art that indicated an appreciative study of nature in different phases. There were admirable figure pieces, the leading one of which would be a rare subject for a painting. In the landscapes the effects produced were so thoroughly artistic that one might infer that the photographers had given special study to Corot, Daubigny, and Duprey, including Constable, the father of them all. Here, in this collection, is a marked example of the rapid progress of photography through the camera clubs of the country. If the works of the Boston, the Cambridge, and other noted clubs should be analysed, the influence of the intellectual and spiritual powers on the progress of photography would surprise the devotees of the art. The progress of the professional photographers, under the same conditions, was apparent to the writer in the Exhibition at Copley Hall, last summer. When he viewed this Exhibition, he saw mind; and when he stood before the Convention he saw that he was addressing men of thought.

It was on this mental basis that a French Judge passed judgment in favour of photography as an art. This is very significant; for questions of law are decided—not on mere theories—but on principles founded on incontrovertible truths. Judges cannot be governed by prejudice; they must decide from facts, and truth is evolved from them.

In a recent case brought in one of the French Courts the old question whether photographic portraits are works of art was revived. It seems a trader in issuing one of his prospectuses had used, by way of embellishment, the portraits of a number of actors and actresses, copied from photographs taken by M. Reutlinger, and he had sent copies to the persons represented. There was no doubt that they approved of the copying, but had they any right in the photographs? After a long course of argumentation the Court decided in favour of the photographer. He was declared to be an artist in the eyes of the law, his art consisting in the posing of the figures, arrangement of the lighting, and selection of the suitable moment for seizing the likeness. He had copyright in his plates, and the person represented, whether he had paid or not for the photography, could not authorise a reproduction of the plate. It was only by a written agreement that the right could be ceded. The photographer was awarded 500 francs as damages and the issue of the prospectus was prohibited.

With a comprehensive mind the Judge framed his decision upon statutory law—the law of nature and the law of common sense. This decision goes to the root. It is for the photographer to show that the growth from this root shall be an inspiration to man.

All art is raised to its sublimest heights by the sacred element; photography is not excepted from this law. The means for rendering nature being perfected, the facts produced must be vitalised with inspiring thought. There can be no cessation of mental action, for thought is ever active to enrich these facts with ideal conceptions. The higher the motive, the nobler will be the results. This truth is being demonstrated by professional and amateur photographers of Europe and America. The action of the imagination is so complex and incomprehensible, it is impossible to define its limits. It concerns mechanical invention as well as the ideal.

Thus far the æsthetic element of photography has advanced with the mechanical. The increase of facility through science widens the field of the imagination. The inventions of science are appropriated and made to serve the ends of æsthetic thought. In photography the practical and ideal will co-operate. The ideal inspires science to further discoveries, and science gives wings to the ideal for higher flights. The inspiration of the painter is enhanced by the enlargement of the means of expressing himself. So with the photographer. The character of his production depends not on manipulation. As with painting, manipulation may increase the artistic effects or general technique, but the operator who is gifted with mental power and spiritual refinement will select his scenes in nature with atmospheric effects, and picturesque shadows, with equally picturesque compositions, that shall express his thought—combinations which a superficial mind would not even notice. In the posing of heads and figures, and adjusting them in forcible effects of chiaroscuro, the results will accord with the comprehension of the operator. No manipulation will change the conditions. The Daguerreotype presents marked evidence of this truth, for in the process of its development no manipulation is possible. One Daguerreotype, from which photographs are now taken, is presented as an eminent example of strong effects produced by

power of mind. The writer referred to a portrait of Judge Shaw, taken by Southworth & Hawes. The Judge himself was a tower of strength, but it required a strong intellect to produce the remarkable Daguerreotype which we now see represented by the photographs. The pose and light and shade are indicative of power comprehending power. William Hunt's portrait of Judge Shaw is a strong one, but in Southworth & Hawes' portrait is the absolute power of a crag vitalised by a human spirit. We can find nothing in the boldest work of the boldest portrait painter that equals this work for its expression of supreme power. That this was no accident is evinced by Southworth & Hawes' Daguerreotypes of Daniel Webster, Ralph Waldo Emerson, and other eminent men. The female heads of these Daguerreotypes were no less remarkable for their beauty in pose and chiaroscuro. They saw and they knew. They produced their work with minds of comprehension.

Certain sceptics affirm that art has nought to do with religion. On the contrary, the highest art of all ages has been founded on religion. When we consider that the soul of man finds true life only through religion, we can understand that art, which is born of the soul, finds in it the highest development. All the arts—music, poetry, architecture, painting, sculpture, and photography—are subject to this law. Through the profane they crawl on the earth; by the sacred element they ascend heights of inspiration.

DARIUS COBB.

### PHOTOGRAPHY IN MANILA.

WHEN I first entered Manila in August 1898, I was very much surprised at the number of photographers doing business in the city.

There are only two English-speaking artists in the city, and they are generally kept so busy that it is impossible to learn anything from them. I have, however, been enabled to learn a little of their mode of work, materials used, &c.

The paper they use is the same as our own—collodion, except that it takes a longer time to print and will not stand burnishing. As a rule, writes Mr. J. D. Joseph to the *St. Louis and Canadian Photographer*, they squeegee all their work. They claim that the climate here is too hot for the American papers, notwithstanding the amateurs in the army use every variety of makes.

The retouching of their work is miserable. In fact, they have been so busy since the entrance of the American army that they make little pretence at retouching. The retouching is done mostly by natives, and for their work they receive only \$20 (Mex.) a month. It is little wonder that their work is not of the finest. They have very poor operating rooms, and, even when one is lucky enough to possess a good room, he makes little use of his skylight arrangements. They have one pose for all subjects, or rather they do no posing whatever.

The instruments used are mostly of German make, and not of the best. Some of the natives have very good lenses, but all the other trappings are very poor.

Their prices are high, the cheapest picture, a little two and one-half by four, being sold at four pesos, or two dollars gold, per dozen.

Notwithstanding all this, however, there is no other business in Manila that has flourished since the entrance of the Americans as that of photography. The soldiers, especially the volunteers, have a weakness for photos, as the photographers of San Francisco and other cities that ever were headquarters for troops can testify. No difference how low the finance of the soldier, he must have his pictures taken, and he does not quibble over the price.

If a competent American photographer had followed the Americans to Manila, he would now be on the high road to wealth, and, although the departure of the volunteers will take away the best customers, still Manila is a good field for a young photographer. Many amateurs in the army have made quite a rich sum for themselves, besides securing a very fine collection.

### COHEN'S IMPROVEMENTS IN GRAPHOSCOPES AND STEREOSCOPES.

At the top of a tripod or pedestal, A, is an open bearing, B, in which is mounted a spindle, C, enlarged at the point where it rests in the bearing, D, so as to form a ball-shaped pivot joint. E. The spindle, C, is held balanced in the bearing by means of screws or the like, F,  $\pi^1$  (fig. 5), and on its front end, which consists preferably of a tube, is furnished with a slot, R (fig. 3), and is closed by means of a knob, button, nut, or the like, O. The lens-holder, X, has a sleeve,  $\pi$ , arranged to slide on the spindle, C, being guided in the slot, R, by means of the indentation, I, and a vertical pin, L, taking into a slot in the handle of the lens, M.

The spindle, C, is connected with a frame, N, which holds the picture-carrier as well as the changing or sliding apparatus.

This changing or sliding apparatus is composed as follows:—

In the upper part of the frame, N, are ears or lugs, O, O', through which the regulating screws, P, P', pass. In the lower part of the frame, N, are other lugs or ears, R, R', serving to receive the driving apparatus or apparatus for rolling up the pictures. This consists of a driving wheel,

s, with or without a crank,  $\tau$ , fixed on a short spindle,  $s$ , and furnished with a cone,  $s^1$ , and polygonal end,  $s^2$ . The polygonal end,  $s^2$ , on the spindle takes into a socket or slot in the lower end of a roller,  $v$ , furnished with a radial groove,  $v$ , for fixing the sliding or changing picture,  $w$ . The screw,  $p$ , is formed with a conical end and is screwed against the end of the roller,  $v$ , so that the roller rotates thereon. The screws,  $p$ ,  $p^1$ , are then fixed by set screws,  $q$ ,  $q^1$ .

For the fixing of the picture-carrier, the frame,  $x$ , is furnished with two studs,  $x$ ,  $x^1$ , to which two rods,  $y$ ,  $y^1$ , are fastened by screwing or in some

other manner, and, for securing spring action, bent somewhat slightly inwards. Over the rods,  $y$ ,  $y^1$ , the picture-carrier,  $z$ , shown in dotted lines in fig. 1, is pushed, its side edges being bent over the rods, and its lower edge also being bent to form a support for the picture.

The action of the whole apparatus is as follows:—

The sliding or changing picture,  $w$ , is strengthened at the ends by being folded or doubled; it is fixed in the groove,  $v$ , and then rolled on the roller,  $v$ . The radial arrangement of the slot ensures the picture being held perfectly tight, so that, when unrolled, it cannot slip off the roller. As one of the rollers is employed for rolling the picture on, and the other for unrolling it, both of them must be so arranged that the grooves do not lie in the same direction. It is obvious that the pictures can be fastened to only one of the rollers, and pass round the other, which in this case serves as a guide, the two ends of the picture being placed in the same slot, which can easily be done without any alteration.

After the picture has been inserted and attached to a roller, the rollers are pushed over the polygon-shaped part,  $s^1$ ; the screw,  $p$ , is screwed into the roller and secured by means of the set screw,  $q$ .

If, now, the wheels be rotated directly, or by means of the crank, the picture can be wound on and off the one roller on to the other, so that, if the lens has been duly adjusted beforehand, the picture will appear on an enlarged scale, and, in the case of a stereoscope, with realistic effect. The picture is moved over the picture-carrier. If the picture-carrier is to be used for simple pictures only, it is adjusted, as regards height, in accordance with the size of the picture, any position given to it being secured by the spring action of the sliding rods,  $y$ ,  $y^1$ .

The arrangement of the balance or rocking shaft in the tripod or pedestal serves to place both the spectator and picture in the proper light as well as to place the picture at a suitable height.

#### TEED'S METHOD OF FOCUSING.

MR. TEED gears the mechanism for focussing with the mechanism of a range-finder, of the type in which the baseline is contained in the instrument, so that the operating of the range-finder actuates the focussing mechanism in such a manner that the lens is in focus for objects at the range chosen. One method of carrying out this invention will be understood by reference to the accompanying drawings. Fig. 1 shows the relative position of the chief parts of the device in plan, but with the plate,  $x$ , removed. Fig. 2 is a section of the device taken through the line,  $x$ ,  $x$ .  $A$  is a guide upon which slides the sliding piece,  $a$ . The lens of the camera is attached in any convenient manner to  $b$ , and travels with it, being actuated by a rack-and-pinion or other suitable means.  $c$  is another guide parallel to  $A$ , upon which slides the piece,  $d$ .  $e$  is a lever slotted at each end and pivoted at  $s$  to the piece,  $p$ .  $p$  is a sliding piece which may be fixed in any desired position upon the guide,  $a$ ,  $a$  being rigidly fixed to the plate,  $x$ .  $l$  is a pin fixed to the piece,  $b$ , and working in the slot at one end of the lever,  $j$ .  $m$  is a pin fixed to the piece,  $d$ , and working in the slot at the other end of the lever,  $j$ .  $t$  is a screw fixed in a bracket on the sliding piece,  $d$ . The point of the

screw,  $t$ , is in contact with a cam-shaped piece,  $z$ , which is pivoted at  $q$ , and kept in contact with the screw,  $t$ , by means of a spring.  $g$  is a mirror fixed to the piece,  $z$ .  $h$  is another mirror fixed to the plate,  $x$ . The reflecting surfaces of the mirrors are towards each other, and  $g$  is so arranged that, when the lens is in focus for objects at an infinite distance, the mirror,  $g$ , is parallel to the fixed mirror,  $h$ .  $r$  is a bright finder, suitably placed for viewing the mirror,  $h$ . The reflecting surface of the mirror,  $h$ , only extends to the line opposite to the centre of the finder, the other half being clear glass. The movable mirror is geared with the focussing mechanism in such a manner that the image of any object shall be in focus in the camera when the portion of the object viewed after reflection from the two mirrors shall, as nearly as possible, form a continuous image with the portion of the object viewed directly. The curve of the cam,  $z$ , is, for convenience, worked out for a certain focal length of lens in conjunction with the baseline of the range-finder, so as

to have the two leverages,  $m$ ,  $s$ , and  $s$ ,  $l$ , equal, but, if it is desired, subsequently to use a lens of any other focal length, the leverages,  $m$ ,  $s$ , and  $s$ ,  $l$ , are made proportional to the focal length of the original lens, and the focal length of the lens substituted respectively, by shifting the position of the sliding piece,  $p$ , along the guide,  $a$ . The curve of the cam,  $z$ , may be obtained for a lens of any particular focal length, either by trial or by calculation. If by calculation, the angle through which the mirror,  $g$ , must be moved from its position parallel to the mirror,  $h$ , for any particular range must be combined with the distance through which the lens must be moved from its position at focal length from the focal plane to the focussing position, using for the calculation the well-known properties of lenses.

#### ORTHOCHROMATIC PHOTOGRAPHY—A REMINDER.

IN *Dry Plates* for August Mr. Cadett has the following notes on this subject:—

As time goes on there will be many who will be sorry that they did not (in its strictly scientific sense) take up orthochromatic photography before. In speaking of orthochromatic photography in its scientific sense our meaning can be taken in two ways:—

Firstly, where the photographer investigates the theory of correctly rendering all luminosities, and combines theory and practice. Comparatively few will, of course, do this, though it is a pity that it should be otherwise.

Secondly, where the photographer leaves science to the manufacturer, and contents himself with getting supplies of materials in the way of plates and light-filters that will enable him to render luminosities correctly without troubling his head as to the why and wherefore.

It is to the latter individual that I make an appeal. Many years ago, when a student in a mathematical class, the professor, looking at the row of anxious and in many cases despairing faces, bid them take comfort. Said he: "Most people incapable of understanding the why and wherefore of many difficult subjects have, nevertheless, excellent capabilities as regards practical use. It is not necessary to understand watchmaking to use and appreciate a good watch. It is not necessary to understand

the theory of logarithms in order to use them; indeed, there are thousands of individuals using logarithms constantly who if asked the nature of them could not tell you. We can use good lenses without understanding the curves, refractive indices, and dispersions of the materials used."

So, in a similar way, it is possible to obtain the most beautiful results in orthochromatic photography, provided the photographer has innate artistic feeling without worrying his head about theories.

I do not say that ignorance, generally speaking, has not its evils. In the case of orthochromatic photography it has been the cause of acceptance of conditions generally that have brought orthochromatic photography into disgrace. Light-filters have been used and put on the market for many years which have been a simple farce so far as correct rendering is concerned. Any piece of yellow glass has been considered good enough by many people, quite oblivious of the fact that all luminosities should be correctly rendered. A light-filter, in the orthochromatic sense, is simply a compensator for the imperfection of the plate. Strictly speaking, no light-filter should be required; but, as we must at present have them, clearly they must be adjusted to the particular plate used. This means measurement, either by trial and error, or by strict scientific measurement, and the latter is the only way to place light-filters into the condition of respectable commercial position. I have always objected to the word "orthochromatic," colour having really nothing to do with the matter. Had we called orthochromatic photography correct luminosity photography, there would have been some general education in the name. However, on the principle of conservatism, good or bad, we must, I fear, keep up our bad habits. I am anxious to induce as many as possible to take up orthochromatic photography, not merely because I am commercially interested in it, but as a matter of sentiment as to what is right; and, moreover, the Judges of our various exhibitions have to be taught, for they have been judging blue, violet, and ultra-violet renderings long enough. They will want educating as well as the rest of photographers.

The exquisite rendering of skies in landscapes, and indeed the whole rendering of the picture by correct luminosities, is such that, excepting for instantaneous work, no photography should be done without plates and filters correctly rendering all luminosities. A few trials on flowers will at once convince the most sceptical.

A little advice to beginners in this interesting branch of photography is necessary.

It is not wise to attempt subjects having a greater range of light and shade than can be rendered on white paper, for, though a greater range than this can be obtained in the negative, the print does not render it. This advice applies particularly in attempting work *against* the light. Carefully selected sunsets do not, however, give this trouble.

I hope that, at the forthcoming exhibitions, some interesting work will be shown, and all should remember that "correct luminosity photography" is the photography of the future.

### MOVING PICTURES OF GROWING PLANTS.

THE U. S. Agricultural Department is now making some interesting experiments, in which the moving-picture camera has been utilised. In one of their greenhouses the Division of Vegetable Pathology has an instrument of this kind in operation. It photographs the growth of a small oak-tree. The machine works automatically, taking one picture per hour. At night the exposure is made by electric light. The camera has been running for two weeks, and in about two weeks the experiments will be discontinued. When the series of pictures is completed, it will be possible to reproduce upon the screen the growth of a plant from the time the first shoot appears above the ground until the tree is in full leaf and a foot or more high. Of course, this experiment has no very great scientific value, but it will be an important test of the capacity of the machine, which it is intended to use in watching the progress of plant diseases, blight, parasites, &c. If it is found that the experiments are successful, the agricultural colleges and experiment stations can receive positives which can be thrown upon the screen which will convey many important lessons.

### ZONE PLATES.

At a recent meeting of the Photographic Society of Philadelphia, Mr. Morris E. Leeds called the attention of the Society to the use of "Phase-reversal Zone Plates as Substitutes for Lenses," and showed some of the applications of the process, which he said was of great scientific interest, though not of much practical value. M. Soret, a French physicist, in 1875, constructed a glass plate, having inscribed upon it concentric black circles of constantly increasing radii, proportional to the square roots of the numbers 1, 2, 3, 4, 5, 6, 7, &c., the whole being reduced by photographing until there were about ninety of these rings in a circle about one inch in diameter. He demonstrated the correctness of certain assumptions regarding the wave theory of light, by bringing rays of light to a focus with his zone plate, just as a lens will do. The plate was shown to have the remarkable property of having multiple foci, and it

acted not only as a convex lens, but as a concave lens, causing some of the light to diverge, as if coming from a virtual focus behind the plate.

After briefly explaining the principle upon which the zone plate acted, Mr. Leeds went on to say that Professor R. W. Wood, of the University of Wisconsin, had recently increased the efficiency of the zone plates by carrying out a suggestion of Lord Rayleigh, and producing a plate in which the alternate zones are on an extremely thin film of transparent bichromated gelatine (claimed to be less than  $\frac{1}{1000}$  of an inch in thickness), so that the light waves are given a phase-reversal instead of being screened off, this resulting in a fourfold illumination. Professor Wood has made plates of this character varying in focal length from 5 inches to 70 feet, the disk in the former case being about the size of a small pea. Mr. Leeds showed specimens of the Soret plates and of the phase-reversal plates (the latter of 180, 65, and 13 cm. focus), also photographs made with them, and demonstrated their use as telescope lenses, in one case employing a zone plate for the eyepiece as well as for the objective.

### THE SUPPLY OF METHYLATED SPIRIT.

THE following case was reported in a recent issue of the *Pharmaceutical Journal* :—

At the Exeter Police Court Mr. Charles Edward Rowe, of the firm of Messrs. E. James Rowe & Company, oil and colour merchants, 192, High-street, was summoned by the Excise authorities for selling, between March 12 and April 26, more than one gallon of methylated spirit at a time, to wit, thirty gallons, in contravention of the Spirits Act.

Mr. G. H. Dennis, barrister, of Somerset House, prosecuted on behalf of the Excise authorities, and Mr. G. H. Harris (Messrs. Ford, Harris, & Ford, Exeter) appeared for the defence, and pleaded not guilty to the charge.

Mr. Dennis, in laying before the Bench the facts of the case, said that the Act under which these proceedings were taken stated that, if more than one gallon of methylated spirit was sold by the retailer at one time, the retailer incurred a penalty of 50*l*. The licence to sell methylated spirit as a retailer cost 10*s*., but a methylator's licence, which entitled one to supply the spirit, cost 10*l*. 10*s*. If Mr. Rowe wished to sell more than one gallon at a time, he could take out a methylator's licence. The facts in this case showed that a list sent round by this firm to its customers and the public included methylated spirit. On March 18 last Messrs. Rowe received a requisition from Mr. F. Cutmore, chemist, of St. Marychurch, Torquay, for thirty gallons of methylated spirit. He sent the usual order, signed by the supervisor of the district, which showed that he was duly licensed to receive the goods. Messrs. Rowe received this order, and they sent a communication thanking him for the same, and intimating that they had ordered it to go forward to Messrs. Preston, of Liverpool. They also asked Mr. Cutmore to alter the name of the methylator on the counterfoil of the order; they had already done so on the order itself. The goods were duly supplied by Messrs. Preston & Co., and on April 11 the defendant sent the account, amounting to 4*l*. 11*s*. 8*d*., excluding discount, to Mr. Cutmore. This showed that a contract had previously been entered into with the defendant to sell. Messrs. Preston & Co. also sent an invoice to Mr. Cutmore. He (Mr. Dennis) submitted that the defendants clearly accepted the order, and entered into the contract to sell. The law was distinct on the question of supply and sale.

The Chairman (Mr. J. W. Petherwick) : Are the facts admitted?

Mr. Harris : With one exception, and that is that the invoice referred to from Messrs. Preston & Co. was sent off at the same time as the spirit, and, of course, arrived before.

Mr. Harris, in defence, said that the sole question in the case depended mainly in what order the facts occurred. His friend argued that there was an acceptance of the order; and he would say distinctly that a careful examination of the facts showed that there was no acceptance of the order from Mr. Cutmore, but that the defendants assisted in making a contract between a third party. If they looked at the letter sent to Mr. Cutmore, they would notice that he said he was "obliged for the order for the spirit, and had ordered the same to go forward at once." And then the communication went on, "Will you please alter the name of the methylator in your book to Messrs. Preston, Liverpool; we have already altered your request note." What was the intention in the alteration of the order? Why, the defendant wished to imply that he had no intention to supply the spirit. In the first place he had not got it, and in the second place he had no right to under the Act. On the receipt of the letter, what did Mr. Cutmore do? He probably thought, "Oh, yes, I made a mistake, I should not have ordered from Rowe, but from Preston & Co. I'll alter it in my book." Whether Messrs. Rowe had a right to pass on Mr. Cutmore's order to Messrs. Preston & Co. had nothing to do with the Excise authorities. He would also draw the Magistrates' attention to the fact that the first words on the invoice sent by Preston & Co. were "Bought of Messrs. Preston & Co." His friend had tried to convince the Bench that there was a contract before the order was sent on to Liverpool, but he (Mr. Harris), said that it was exactly the reverse. Messrs. Rowe's letter to Mr. Cutmore was to the effect: "No, we cannot execute the order, but we will send it on for you

to Messrs. Preston & Co., and we will alter the order." Supposing the order was originally made out to Messrs. Preston & Co., what could the Excise authorities have done then? Surely Messrs. Rowe would not have had anything to do with it. The summons might in that case be just as well taken out against the Postmaster-General for forwarding the order. With regard to the sending of the bill to Mr. Cutmore by the defendants, he (Mr. Harris) said that had nothing whatever to do with the contract. Mr. Dennis had said that the contract had been entered into when the defendants received the order, and had dealt mainly on that fact. The Magistrates had simply to consider the case as set before them by the prosecution, and, if the contract was entered into as Mr. Dennis had alleged, then what came afterwards did not bear upon it.

Mr. Dennis submitted that the alteration in the permit was made in order that no inquiry should be made by the inspector, who, if the permit did not correspond with its counterfoil, would naturally investigate.

Mr. Harris said that Mr. Dennis had no right to make such remarks unless he could prove them.

The Bench were of opinion that there had been a sale of spirit, and inflicted a fine of 5*l.* inclusive.

#### COPYRIGHT IN TRADE-CATALOGUE ILLUSTRATIONS.

An action was brought before Mr. Justice Grantham, on Friday last, by Croft & Perkins of the Great Northern Works, Bradford, Engineers, against Carter Bros., Engineers, Rochdale, for damages for infringement of copyright in a certain illustration included in their machinery catalogue. Mr. Scott Fox, Q.C., and Mr. Waugh were counsel for plaintiffs; and the defendants were represented by Mr. E. Tindal Atkinson, Q.C., and Mr. H. Manisty.

It appeared that the illustration in question was produced in the year 1890, and the catalogue was circulated amongst the trade. Plaintiffs claimed that, having made a certain article, of which they had taken a photograph, and reproduced it on a wood block and printed it in their published catalogue, they had the right to the exclusive use of the reproduction. Plaintiffs' catalogue was republished in 1892 and 1897, and in 1898 the illustration now the subject of the action was found reproduced in the defendants' catalogue and trade advertisements. It was the representation of an adjustable hanger.

Mr. Atkinson contended that this could not be the subject of copyright under the Act of 1842, inasmuch as no literary, artistic, or mental effort had been requisite to produce the plaintiffs' picture. Photography, he urged, had been dealt with in a separate Act of Parliament. The defendants' illustration had been taken from one sent in by a customer, and no doubt, he said, it was a copy of what originally appeared in plaintiffs' catalogue; but, counsel went on to remark, even Turner's sunsets were not a copy of nature.

His Lordship: That's very true. They're an improvement upon nature. Then you mean that the picture of this article is not at all like the original?

Mr. Atkinson: I don't say that.

One of the defendants, in cross examination, admitted that, although his firm had made a great number of adjustable hangers, they had not produced one of the design illustrated until a customer sent them the picture referred to. He had not seen the drawing in plaintiffs' catalogue.

His Lordship thought the case one of considerable importance. The matter was small, but the principle involved was great. He considered himself bound by the decision in the case of *Maple & Co.* and the *Junior Army & Navy Stores*. If he were to hold that the plaintiffs could not claim copyright, he should be opening the door to a great deal of fraud, considering the amount of illustrated work produced by the Press. The fact that the illustration was bound up with others in a book brought the case within the scope of the Literary Copyright Act. He found a verdict for the plaintiffs, and gave judgment for 40*s.* and costs; also, the defendants must undertake to withdraw from publication the catalogue containing the objectionable illustration, and undertake not to publish any more containing it.

#### THE SOUTH LONDON SOCIETY'S EXCURSION TO IRELAND.

The members forming a party for a trip extending over eight days in Ireland left Euston in reserved compartments at 6.30 p.m. on July 28, and, after a speedy journey from Holyhead across St. George's Channel, arrived in Dublin the following morning. The headquarters were at the Hamman Hotel, Upper Sackville-street. Here, after breakfast, the excursionists, which included ladies, were met by Mr. Victor Smyth, Vice-President of the Photographic Society of Ireland, who acted as chaperon for a part of the day, pointing out the principal buildings in the city of Dublin, and explaining their points of interest. Among other things, the "native" mummies in the vaults of St. Michan's Church were seen. Although of some considerable antiquity, these mummies do not compare in point of age with their Egyptian or Peruvian congeners, and their preservation is due to a natural process, and not to artificial methods. In the afternoon a trip was made by steam tram to the beautiful Lucan demesne, where many exposures were made. The Spa

water was tested, and varying verdicts passed thereon. Next morning cars were chartered for a long trip round Phoenix Park and the northern part of Dublin, including all the principal points of interest. In the afternoon the train was taken to Malahide, and a visit paid to Swords, with its round and Norman towers, and the ruins of an archiepiscopal palace. The evening was spent on the strand and beach of Malahide, where fine sunset effects can be obtained. On the station platform some amusement was caused by the Hon. Treasurer being mistaken for Dr. W. G. Grace, whom he resembles. At nine o'clock the following morning the party joined the Northern express for Drogheda, where specially chartered conveyances met them at the station for a drive of twenty miles round the Boyne Valley. The first stop was at Boyne Bridge, the site of the famous battle. The cairns (or, as they are sometimes called, caves) at Dowth and Newgrange were visited, and their archaic carvings inspected by candle light. The entrance passage at Newgrange is sixty feet long. Some considerable time was spent at the ruins of Mellifont Abbey, the oldest Cistercian remains in Ireland, after which the Monasterboice, with its ruins and far-famed crosses, &c., were photographed. Rather less than a mile from the latter place the excursionists were rewarded by an extremely fine view of the Mourne Mountains in County Down. The descent into Drogheda was made by the North Coach Road, and the night was spent in the town at the White Horse. The interesting remains of the old buildings left by Cromwell were duly photographed. On Tuesday morning a trip to Kell's by rail took place. Due justice was done to the crosses, the round tower, St. Columbkille's house, &c., after which the Boyne at Headfont Bridge was visited. Being unable to tear themselves away in time resulted in a large portion of the party missing the train, and causing them to beguile away an additional three and a half hours in the town, which, according to all accounts, they managed to do with good results. Tuesday night was spent in Dublin, and at ten o'clock on Wednesday a start southwards to County Wicklow was made. Bray, the Brighton of Ireland, was the first stopping place. Many exposures were made about the town, and after lunch jaunting cars took the party to the Dargle, where all available time was spent before dinner at the Bray Esplanade Hotel.

The following morning saw the party off to Rathnew, where cars were engaged to take them to a convenient point for visiting the Devil's Glen. The general opinion was that this valley was finer than the Dargle, and had the advantage of a good road alongside the greater part of the stream. The train was rejoined at Rathnew. At Rathnew Station special conveyances met the excursionists to take them to lovely Glendalough (seven churches), eight miles distant, where they arrived in time for dinner. Two nights were spent at the Royal Hotel. Friday was occupied in photographing about the lakes, the glen, and its numerous ruins and antiquities, which are of a character not to be found outside Ireland. On Saturday morning all left for a nineteen-mile drive across the mountains into the Wild Glenmalur, passing the untenanted Drumgoff Barracks, erected after the lively episodes of 1798 in this valley. Ultimately a stay was made at the Meetings Bridge, where the plaintive melody, "The Meeting of the Waters," played by the blind flautist Billy Kelly, was listened to. The journey was continued down the Vale of Ovoca as far as Woodenbridge, where the train was taken for Dublin. After the final dinner at the Hamman Hotel, the s.s. *Cambria* was rejoined. The excursionists arrived at Euston shortly before eight on Sunday morning. Here the party broke up with regrets that the time had been so short, but the regrets were tempered by the thought that much had been seen and done in the time, and that they would in the dark room and elsewhere live the trip which they had much enjoyed over again. Throughout, favourable and suitable weather prevailed, with the exception of a "wee skiff" lasting five minutes. Although fine, the weather was temperate, so that excessive heat was not complained of. The subjects dealt with during the outing were of a most varied, interesting, and pleasing character, and many fine pictures are expected to result from the exposures made.

The arrangements with the hotels were excellent. In the course of the drives the road was at times diverged from owing to the proprietors of some large demesnes permitting the conveyances to pass through their estates.

A desire was largely expressed that other trips to Ireland, under the leadership of Mr. Howard Esler, who is a native, will be arranged in future years.

## Our Editorial Table.

#### CONVENTION PHOTOGRAPHS.

By Mr. Alfred Seaman, Chesterfield.

ACCOMPANIED by his faithful stereoscopic camera, Mr. Alfred Seaman, the well-known photographer of Chesterfield, Ilkeston, and Sheffield, was, as usual, a genially prominent figure at the Gloucester Convention. He touches a soft place in our hearts by sending us a series of binocular photographs taken by himself during a very pleasant week. These include views and groups at Berkeley Castle; groups and interiors at the delightfully old-world New Inn Gloucester; boat on the Severn &c. Stereoscopically regarded, these pictures are all that could be desired: the

separation distances are in each case under three inches; the subjects are well chosen and the mounting correct. Thus, besides being most agreeable reminders of the Convention, they are also binocularly good. We wish Mr. A. Seaman's stereoscopic photographs the success they deserve.

#### KACHIN.

John J. Griffin & Sons (Limited), Sardinia Street, W.

FROM MESSRS. J. J. GRIFFIN & SONS we have received samples of kachin, the latest of the new developers, as they are now supplying it. There are the crystals themselves, and a concentrated solution, which only requires to be diluted with water to be ready for use. The former is put up in one and four-ounce tins, and half and one-pound bottles, the latter in tubes packed in boxes containing three, or one dozen each, price 1s. and 3s. 6d. respectively. The price of the salt is 2s. 6d. an ounce. Although this price seems high as compared with pyro at 1s. an ounce, there is little doubt, as the solutions keep well and can be used over and over again, that it is really cheaper in the end. Among the claims made for kachin, as set forth in the prospectus, are: It is capable of producing extreme softness or strong density at will; it is not influenced by the addition of hyposulphite of soda; by combining the processes of developing and fixing the most brilliant results are secured, making this method a unique remedy for over-exposure, and giving greater play in exposure; it is easily soluble in water, and is not influenced by temperature; it does not stain the fingers or plates, nor does it affect the skin; it is extremely economical, because the solution can be used repeatedly, and will retain its vigorous qualities even after continued use; it will produce negatives of great range of density, by different degrees of dilution, giving soft or hard results according to the nature of the subject; it gives clear, black-grey negatives, with perfectly clear shadows, even after prolonged immersion; it is very sensitive to the addition of bromide of potassium as a restrainer; it has the most durable keeping qualities, whether used as a single or two-solution developer.

Our experiments with kachin quite substantiate these claims. Here are the formulae for the use of this new developing agent:—

#### KACHIN-PHOSPHATE DEVELOPER.

##### Solution A.

Sulphite of soda	
cryst. ....	25 grammes, or 385 grains (avoirdupois).
Kachin .....	5 " " 77 " "
Water .....	250 " " 8 ounces "

##### Solution B.

Phosphate of soda	
cryst. ....	47 grammes, or 725 grains "
Caustic soda (purified in sticks)...	5 " " 77 " "
Water .....	250 " " 8 ounces.

These solutions will keep indefinitely.

**For Plates.**—For use, take 1 ounce of A, 1 ounce of B, and from 1 to 3 ounces of water. The full-strength developer gives the most vigorous images, and is suitable for snap-shots and normal exposures; the more diluted developer gives softness and half-tone. Bromide of potassium need only be used to correct excess in over-exposure. A single drop of a ten per cent. solution materially modifies the action. For under-exposures increase the proportion of B solution.

**For Bromide Papers.**—Take 1 ounce of A, 1 ounce of B, 6 ounces of water, and 9 drops of bromide of potassium (ten per cent. solution). In order to obtain deep black tones, add 20 to 40 drops of yellow prussiate of potash (ten per cent. solution).

#### CONCENTRATED DEVELOPER (ONE-SOLUTION).

Sulphite of soda	
cryst. ....	100 grammes, or 2 ounces, or 262 grains (avoirdupois).
Caustic soda (purified in sticks)...	14 " " 173 " "
Kachin .....	20 " " 247 " "
Water .....	400 c.c. " 10 ounces "

For use, the concentrated developer is diluted with from ten to twenty times as much water. Diluted with the smaller quantity of water, the developer works quickly and gives brilliant results; with more water, the action is slower and the resulting negatives are softer. The normal proportion is 1 part of developer to 15 parts of water. The addition of bromide of potassium is not necessary except for checking excessive over-exposure.

Do not add the kachin until the sulphite and caustic soda are entirely dissolved. The stock solution may be kept in corked bottles for a long time without deterioration. Slight discolouration does not lessen the active qualities of the developer.

#### CONCENTRATED DEVELOPER (IN TWO SOLUTIONS).

##### Solution A.

Sulphite of soda cryst. ....	50 grammes, or 771 grains.
Kachin .....	10 " " 154 " "
Water .....	500 c.c. " 16 ounces.

##### Solution B.

Caustic soda (purified in sticks)	7 grammes, or 108 grains.
Water .....	500 c.c. " 16 ounces.

For use, take 1 part of A, 1 part of B, and 2 to 6 parts of water. The normal proportion is 1 part of A, 1 part of B, and 4 parts of water. In the same manner as the one-solution developer, the stronger solution works more rapidly and brilliantly than the more diluted one. For under-exposure and more rapid development, increase the proportion of B solution.

#### FORMULA FOR DEVELOPING AND FIXING.

##### Stock Solution.

Sulphite of soda	
cryst. ....	80 grammes, or 4 ounces, 135 grains (avoirdupois).
Caustic soda (purified in sticks) ...	7 " " or 1 ounce "
Kachin .....	7 " " 1 " "
Water .....	75 c.c. " 10 ounces "

For fully exposed plates, take—

Stock solution .....	6 drachms.
Hypo solution (1 ounce of hypo to 5 ounces of water) .....	10 " "
Water .....	15 " "

Whatever may be said, theoretically, against developing and fixing at the same time, the above formula has yielded excellent results in our hands. We have no hesitation in saying that kachin is unsurpassed by any of the new developers we have experimented with.

#### "PROFESSIONS FOR BOYS AND HOW TO ENTER THEM."

By M. L. PECHALL and JAMES J. NOLAN. 316 pp. Price 3s. 6d. London: Beeton & Co., Limited, 10 and 11, Fetter-lane, E.C.

WE do not find photography included among the professions which the authors recommend to the consideration of parents troubled by the problem of what to do with their boys. It is probably not considered a "profession" ranking with the stage, journalism, the Stock Exchange, and other branches of genteel labour dealt with in this book. The authors, however, have done their work very thoroughly, and the details given of the many professions, which are described for the benefit of those desirous of knowing what possibilities of success they offer their sons, are full and ample. Dr. Welldon writes a preface to the book, which is well and plainly written.

WE have received an advance copy of the Great Eastern Railway Company's Booklet, giving particulars of the New Tours arranged in the Thuringian Mountains, the Luther Country, and the Hartz Mountains, via the Royal Mail-Harwich Hook of Holland Route.

MESSRS. PERCY LINDLEY & Co., of 30, Fleet-street, send us an advance copy of the London, Brighton, and South Coast Railway Company's *South Coast Quarterly*. This is a well got-up magazine, with photographic illustrations and descriptions of some of the more beautiful places served by the Brighton Line.

#### CATALOGUES RECEIVED.

WE have received the catalogue of a new set of over one thousand lantern slides of Italy, its art, landscapes, cities, and buildings, to which is added a synopsis of twelve former Italian sets made and published by Messrs. G. W. Wilson & Co., Limited, 2, St. Swithin-street, Aberdeen. The catalogue extends to twenty-four pages. The set is recommended by Messrs. Wilson to all lovers of art or of Italy. They point out that teachers—whether of classical literature, Roman history or New Testament history, and lecturers on such subjects as architecture, the Italian school of painting, Ruskin, Browning, &c.—will find that a judicious selection of slides from this set will keep their classes or audiences thoroughly interested. To assist intending purchasers in selecting slides suitable for their purpose, special catalogues of miniature illustrations have been prepared, each slide being shown on a small scale.

The Photochrom Company, Ltd., 121, Cheapside, E.C.

THE latest catalogue of the Photochrom Company is in two sections; the one devoted to foreign views, the other to views taken in the British Isles. The former extends to 112 closely printed pages, the latter to 28. Everybody nowadays knows that a photochrom is a photograph "printed in the colours of nature," and the appreciation in which the Company's beautiful productions are held may be gauged by their wide-spread popularity. Looking through these long lists of attractive subjects, it seems difficult to believe that there are many well-known subjects left for the Company to reproduce in colour; nevertheless, we believe the catalogue is "still growing."

## News and Notes.

A CORRESPONDENT of the *Daily Chronicle* vouches for the accuracy of the following story of *nouveau-riche* ignorance and fussiness. Some time ago a feminine member of this class went into a stationer's shop at Conway, and asked for a photograph of the castle. "Beeytiful castle," she simpered, "but, oh! what a pity they built it so close to the railway station!"

**PHOTOGRAPHIC CLUB.**—Anderton's Hotel, Fleet-street, E.C., Wednesday evening, August 16, at eight o'clock. Discussion: "The Permanency of the Bromide Process." Visitors are admitted to the meetings of the Club on the personal introduction of a member, or by invitation cards which the Hon. Secretary (Mr. W. R. Stretton, 4, Queen-street-place, E.C.) will be pleased to forward on application.

**PENNY IN THE SLOT PICTURES.**—Mr. Samuel Smith, M.P., writes to the *Times*: "Will you allow me to call the attention of the public, through your columns, to a new source of evil which has recently sprung up at our popular watering-places? I refer to vicious and demoralising pictures shown in penny-in-the-slot machines. I have had quite a number of letters in consequence of a question I put in the House of Commons to the Home Secretary. I give, as an example, an extract from one I had from Southport: 'I paid a visit about six weeks ago to a fashionable new arcade in Lord-street, and we entered, out of curiosity, the ground-floor premises of the penny-in-the-slot exhibition. I had three or four pennyworths, and I was literally astounded that the Southport authorities permitted such viciously suggestive pictures to be publicly exhibited. If those at Blackpool and other places are anything like those at Southport, they are a source of great danger to morals. Those at Southport are on the cinematograph principle, and, as the pictures are all moving, it makes them the more dangerous in their influence. Whilst we were in the exhibition, two or three girls were going round.' I understand it is difficult to obtain a conviction unless the outrage is of the grossest kind; but surely the local authorities can, at least, prohibit such exhibitions on the foreshores of seaside places which are under their control. It is hardly possible to exaggerate the corruption of the young that comes from exhibiting, under a strong light, nude female figures represented as living and moving, going in and out of baths, sitting as artists' models, &c. Similar exhibitions took place at Rhyll in the men's lavatory, but, owing to public denunciation, they have been stopped. Is it not possible to do this in other localities? I understand that many houses in London have recently been taken for these exhibitions. If nothing is done to stop this, we shall see a rapid decay of English morals to the level of Paris, with the same deadly results on the life of the nation."

THE forty-sixth report of the Science and Art Department of the Committee of Council on Education, signed by the Duke of Devonshire and Sir John Gorst, contains much interesting information on the work done under the auspices of the department during the year 1898. The volume is exceedingly bulky, and sets forth the detailed reports of nearly every important official connected with the working of the various institutions in which science and art are taught. Dealing first with the science division, the report records a considerable increase in the number of pupils under instruction. For the year 1898 the grants to science schools in England, Wales, and Ireland, exclusive of those made to training colleges, amounted to 169,604*l.* 3*s.* 8*d.* The grants for 1897 amounted to 172,495*l.*, but this included payments to science schools in Scotland which are now made by the Scotch Education Department. In the art division it seems that during the year ended August 31, 1898, 12,041 elementary schools with 1,458,911 scholars were taught drawing and examined under the regulations of the department. In the previous twelve months ended August 31, 1897, the number of schools examined and of scholars taught was 20,493 and 2,286,431 respectively. A paragraph in the report in reference to the art division, which will be read with great interest, deals with the grants allowed by the department. It seems that the payments on results and attendances for England, Wales, and Ireland amounted in 1898 to 72,128*l.*, as against 79,716*l.* in 1897, of which the grant for Scotland was 10,024*l.* The average payment per student under instruction in England, Wales, and Ireland for 1897 was 10*s.* 9*d.*, while in 1898 it was 11*s.* 11*d.* This increased rate is due to increased efficiency in instruction and improvement in accommodation and equipment of rapidly developing schools. The change in system from payment on results to payments on attendances (with payment for works and on results only, in honours, and subjects kindred thereto) resulted, with a few exceptions, in the allocation to the schools and classes of amounts of grant equal to what they would have earned under the old rules of payment.

## Patent News.

THE following applications for Patents were made between July 24 and July 29, 1899:—

- PHOTOGRAPHIC APPARATUS.**—No. 15,412. "An Improvement to a Photographic Apparatus." E. M. M. SMITH.  
**COLOUR PHOTOGRAPHY.**—No. 15,444. "Improvements in Colour Photography." W. N. L. DAVIDSON.  
**PERSISTENCE OF VISION.**—No. 15,496. "Improvements in Apparatus for Testing the Exact Duration of Persistence of Vision on the Human Retina." E. S. BRUCE.  
**CAMERAS.**—No. 15,563. "Improvements in Photographic Cameras." R. KROGNER.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
15.....	Hackney .....	A Plea for Fuzzy'types. For: W. Rawlings. Against: F. W. Gosling.
16.....	West Surrey .....	Demonstration: Developing P.O.P. C. Sheed.
16.....	Photographic Club .....	Discussion: The Permanency of the Bromide Process.
19-26 .....	Ashton-under-Lyne.....	A Week's Outing to Helensburgh and the Scotch Lakes.
19.....	Hackney .....	Excursion: Woolwich. Leader, H. W. Dunkley.
19.....	Oldham .....	Excursion: Chew Wells or St. Chad's. Leader, H. Varley.
19.....	Borough Polytechnic .....	Excursion: Wimbledon Common. Leader, R. B. Rawkins.
19-27 .....	Droydon Camera Club .....	Excursion: Belgium. Leaders, Messrs. Welford, Slater, and W. H. Rogers.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 3.—Mr. A. Mackie in the chair.

Mr. J. W. HODGES passed round a quarter-plate which had been exposed in a hand camera and developed in the usual way. The result, however, was a positive instead of a negative. The plate had been brought to him for an explanation of the phenomenon, and he could not give an exact account of its treatment.

Mr. J. S. TEAPE said the result was similar to that he had obtained with some hand-camera exposed plates of his own, and he had shown them at a previous meeting of the Association. In his case the developer was metol, and he had developed several plates simultaneously in the same dish. Some turned out good negatives, and others were positive pictures, as in the example shown.

Several suggestions were made as to the possible cause, none of which would, however, apply in Mr. Teape's case. One of the suggestions was that a similar result might be obtained by exposing the plate, after development had commenced, in the usual course to sufficient light to produce a stronger action on the plate than the original exposure, the reduced image protecting the part originally acted on. On continuing development, the result would be a positive.

Mr. E. J. Wright passed round a half-plate negative of the interior of a room. Each of the bottom corners of the negative was densely fogged. The appearance was similar to what would occur had a lens with a small circle of illumination been used and the front lowered to the intent of leaving part of the plate out of the field, but with a dense deposit taking the place of clear glass.

It was pointed out that, as the part of the plate protected by the rabbit of the slide was clear, the defect could not have arisen before the plate was put in the slide or after it was removed therefrom, and it was suggested that the cause might be discovered by setting up the camera under exactly the same conditions as when the negative was exposed and examining the lens fitting from the back of the camera.

Mr. Featherstone showed some gelatino-chloride prints toned in a phosphate bath made up of—

Gold chloride .....	1 grain.
Sodium phosphate .....	24 grains.
Water .....	24 ounces.

Thirty half-plate prints had been toned in this quantity of bath.

A general conversation took place on matters connected with gelatino-chloride printing, &c.

In reply to a question as to why, when gold chloride was added to a sulphocyanide bath which also contained sodium acetate, the usual blood-red colouration did not occur, Mr. E. BANKS said the colour was due to the formation of sulphocyanide of gold. This was slowly soluble in a solution containing an excess of sulphocyanide of ammonium, but solutions of the acetates and some similar salts dissolved it rapidly.

Mr. C. M. MOSS drew attention to the fact that there was a distinct variation in the tone of prints that had been treated in exactly the same way, except that the washing after fixation had been longer or shorter, and this was still more noticeable after the prints had been burnished.

Mr. W. D. WELFORD said he had been experimentally trying to induce frilling of plates under development. He had tried several brands of plates and various developers, the latter being, however, all of the newer introductions. He had not succeeded, although the recent hot weather had been in his favour. He attributed his want of success partly to the improved manufacture of modern plates, but principally to the developers used, which were far less liable to cause frilling than pyro.

### FORTHCOMING EXHIBITIONS.

1899.

- August ..... One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C.  
 Sept. 22-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.  
 „ 25-Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.

- October 18-24 ..... Croydon Camera Club.  
 " 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
 Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.  
 December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PHOTOGRAPHING MACHINERY.

To the Editors.

GENTLEMEN,—Allow me to offer a word of praise, with reference to your article (in last week's JOURNAL), "Photographing Machinery." I consider it a splendidly written article, and most useful to many, as you say, whose work is chiefly confined to studio work.—I am, yours, &c.,

W. E. FOSTER.

The Vandyke Studio, 17, Bennett's-hill, Birmingham.

### STEREOSCOPIC ILLUSTRATIONS.

To the Editors.

GENTLEMEN,—Your issue just received contains a notice of a work by Mr. Porter, which is illustrated by photographic views for the stereoscope which is supplied.

I have not had the good fortune to see the work, but it has recalled to my mind that, in 1858, the late Professor Piazza Smyth (of Edinburgh) published his experience in Teneriffe, which was also illustrated with stereoscopic views, and accompanied by a lenticular stereoscope. The Professor called attention to the fact that he gave for the first time a true representation of the appearance of the celebrated dragon-tree of Orotava, and compared it with the caricatures produced by artists who had depicted it more or less out of their imaginations. This process is called (euphoniously) putting some of himself into a likeness.—I am, yours, &c.,

J. F. T.

[The August number of the Camera Club Journal also contains the following note on the subject:—

Illustration by means of stereoscopic views is not new; the Club library contains a book on the temples in the Nile Valley illustrated in a similar manner, and published in 1862 by Smith, Elder, & Co. There is a great deal to be said for the stereoscopic form of illustration, but we are not sure that the half-tone process quite meets the requirements. The half-tone pictures, when viewed through a stereoscope, do not look so well as a stereoscopic silver print, as any one can see for himself by comparing the illustrations in Mr. Porter's book with those in the earlier publication.

Mr. Porter must be congratulated on having produced a most interesting work and for his boldness in employing what will be, to many of his readers, a novel form of illustration.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this causes delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

John Bailey, 73, Shirley-road, Southampton.—Three photographs of Victor Barton, Hampshire professional cricketer.

PUZZLED.—Many thanks. We, however, prefer not to publish. The statements invite the criticism you subject them to, but there are reasons why we do not care to have any controversy over the matter.

C. CARTWRIGHT.—Better send the residue to a refiner, as it is quite clear that you do not understand how to reduce it.

ALPHA.—You had better address your query to the Comptroller of Patents, the Patent Office, Southampton-buildings, Chancery-lane, London, who will send you a copy of the specification post free for nixpence. Sorry we cannot afford the time to make the search.

A. LEVY (Paris).—Thanks for your letter. In the peculiar circumstances of the case, which would take too long to explain to you, our correspondent could not possibly benefit by the advice. We reciprocate your good wishes, and hope to have the pleasure of seeing you in 1900.

MARKS ON PLATES.—R. ABELL writes: "I am troubled with scumlike markings on my plates, which are —'s make. They can be clearly seen on the plates before they are exposed. Can you tell me how to avoid them?"—No, we cannot, as the fault is in the plates themselves. They should be returned to the makers, or to the dealer from whom you had them, supposing you had them through a dealer.

STUDIO BUILDING.—P. P. P. says: "I am having a studio built similar to Mr. Debenham's described in Bolas's *Photographic Studio* (chapter ii.), with a pair of doors on the glazed side leading to the garden. Would it be better to have these doors open outwardly or inwardly?"—As the doors are to be at the side, it is quite immaterial which way they open. Make them to open whichever way will be most convenient to you.

SIZING PAPER.—J. WIDDOWSON says: "I should be quite obliged to you if you would give me in your next impression proportions and mode of working for sizing paper previous to sensitising, either starch or arrowroot."—The usual way is to add the sizing material, generally two or three grains of gelatine per ounce, to the salting solution. A small proportion of thin starch or arrowroot paste can, of course, be substituted for gelatine if preferred.

WARM TONES ON PRINTS.—SNAP-SHOT says: "Will you kindly inform me how I may obtain (in photographic prints) that rich, warm tone of brown so much in evidence in photographers' cases just now? Will these tones be as permanent as the old-fashioned purple sepia?"—The tones are obtained by simply removing the prints from the toning bath before they arrive at a darker stage. Opinions are very much divided, and always have been, as to whether brown-toned prints are as permanent as black ones.

FAULTY MIRROR.—PROCESS writes: "I am making some experiments in process work, using a mirror silvered on the surface, but I cannot get a sharp negative with it; there is no crispness. The lens is a Dallmeyer rapid rectilinear, and, without the mirror, the definition in the negative is splendid, but, with the mirror, there is no sharpness."—Clearly the mirror is at fault; its surface is not optically plane. Possibly, however, the glass may be right, but it is pressed too tightly by its mount. See to that. The glass should be quite loose in the mount.

CONTAMINATED.—HYPO. A. W. H. says: "Would you kindly give us an opinion of the following: About two-thirds of a barrel of granulated hypo is turned into something resembling fine cinders and ashes mixed. It is kept in a dry kitchen, and was in good condition some two or three days before we discovered it. In the mean time we had rather a severe thunderstorm. Could that be the cause?"—The appearance is due to the dry atmosphere of the kitchen causing some of the water in the crystals to evaporate. The thunderstorm had no influence.

MEMBERSHIP OF R.P.S.—F. C. M. M. says: "As I wish to become a member of the Royal Photographic Society, will you kindly furnish me with particulars as to what has to be done to join it? Kindly furnish address of the Secretary, also any particulars which will enable me to become a fellow in the event of my not being acquainted with any member. I understand you have to get a reference from two members."—In reply: Address, for particulars, The Hon. Secretary, Royal Photographic Society, 12, Hanover-square, W. We shall be happy to propose you for membership, which is obtainable by election at the hands of members. Fellowship, however, rests with the Council and a special Admission Committee.

MILDEW ON ENGRAVING.—X Y Z says: "Could you kindly inform me if it would be possible to remove mildew spots from an engraving? I have a valuable one, which has got badly marked with round dark spots, which, of course, show worst on the light portions, especially on the sky. Is there any chemical that would remove them without injuring the paper, or would it do to touch them over with water colour?"—The best thing to do is to bleach the print with chlorine, using either the hypochlorite of soda or the hypochlorite of potash. That will entirely remove the mildew from the lights and shadows. But we should advise our correspondent to put the print, as it is valuable, in the hands of an expert in print-restoring, as a novice at the work might ruin the picture. Plate paper, when wet, particularly after the action of chlorine, is as tender as wet blotting-paper, and requires the greatest skill in handling.

REFLECTIONS.—PUZZLED says: "I have been a reader of your paper for many years, and I should be glad if you could explain the following: I have taken several pictures this last day or two of bust and full-length pictures, and, upon each being developed, a reflection of the whole sky-light has appeared on the negative. I have had the subjects and accessories at the far end of the studio, and there is nothing to reflect in the studio. The curious part about it is, they have never appeared before, and I have taken hundreds in the same place without the slightest effect. If you could give me some idea of what is the cause, I should feel favoured."—The "reflection" is no reflection at all, but a secondary image, formed by a hole in the camera or its bellows, which has acted as a "pinhole camera." If the lens be capped, the focussing screen removed, and the camera examined from the inside in a strong light, with the head covered with the focussing cloth, the hole will be discovered; then the remedy is obvious.

## EX CATHEDRA.

THE following announcement appears in a recent issue of a New Quay paper: "Photography. The Studio. Mr. Wallace Bennetto begs to announce that the studio is now reopened for the production of high-class photography. Sittings for portraits and groups daily. The studio will shortly be open for the production of portraits in colours direct from life. Further announcements will be made."

\* \* \*

WE are gradually accumulating quite a large collection of mystery photographs. By mystery photographs we mean pictures showing technical phenomena difficult or impossible of explanation. For example, some time ago a gentleman sent us a photograph of a horse which apparently only possessed three legs. In reality he had four, but the photograph said otherwise. No satisfactory explanation of this little mystery appeared to be forthcoming. The very commonest kind of mystery photograph appears to be the portrait through which a portion of the background, wall, or furniture, is seen to be visible. Movement or pre-exposure would appear to account

for such phenomena, but the photographs are usually of such a nature that it is obvious that no movement could have taken place. One of the most remarkable photographs of this kind we have recently seen was one of a natural history specimen taken in a museum. The specimen stood on a wooden block, which was apparently transparent to the lens, for an inscription on the other side of the block of wood appeared in the photograph as if the lens and the sensitive plate had penetrated right through the support.

\* \* \*

SOME time ago a friend of ours showed us a print from a negative taken by himself which caused him a considerable amount of mystification. He was photographing in the country with a small French binocular camera, and the resulting print showed that he had photographed himself arms akimbo, as one's position naturally would be with a camera of the kind described. All sorts of explanations were forthcoming to account for the puzzling affair, but none met the case. At last it was suggested that the position of the sun was at the bottom of the mystery. The photographer's shadow had been cast immediately in front of him while the camera was up to his eyes, and he had released the shutter not observing the immediate foreground and the silhouette of himself which it bore. But it was months before this simple theory was broached, and, in the mean while, others besides our friend had been nonplussed to account for the supplementary shadow in the photograph.

\* \* \*

IT is, of course, well known that a pinhole in the front or the bellows of the camera is very frequently responsible for supplementary images in photographs, but the cases we have in mind at the moment do not fall in this category. No; we are confronted by real mystery photographs, the phenomena of which are not explicable on ordinary grounds. Doubtless, many of our readers are at times bewildered in a similar way, and we should be glad to hear of such cases, accompanied, if possible, by specimen prints. To avoid misunderstanding, we may say that we are not inviting so-called spirit photographs, of which we possess quite as many as we care to have. What we want, in short, are photographic mysteries that are apparently impossible to solve.

A FORTNIGHT ago we mentioned the fact that a memorial to the late Dr. Ferdinand Hurter, taking the form of a lecture, was being organized by the Society of Chemical Industry, of which he was long a valued member. The photographic world is invited by the Hon. Secretary of the Royal Photographic Society to subscribe a sum of about 50*l.* towards the memorial, and we have no doubt that amount will be forthcoming. Dr. Hurter brought a highly trained mind to the study of photo-chemistry and photometry, and the work he and his esteemed colleague, Mr. V. C. Driffield, accomplished in the attempt to provide a practical system of estimating the speed of plates was of the very highest scientific value. We are sure that so long as photography exists Dr. Hurter's name will be appreciatively remembered, and it is fitting therefore that, in the endeavour to perpetuate his memory in the larger chemical world of which he was a prominent figure, photographers should claim the modest share they have been invited to take.

\* \* \*

THE widow of the late Mr. W. B. Bolton has the following apparatus for disposal. If any of our readers are disposed to buy from the list, we shall be happy to forward their letters to the gentleman who is undertaking the sale.

ROSS No. 3 WIDE-ANGLE SYMMETRICAL (No. 57,693).—5 in. focus, rotating diaphragms (*f*16 to *f*64). Covers half-plate with full aperture, or whole-plate with smaller stops. As new; only used three times. Cost 3*l.* 15*s.*; will sell for 2*l.* 15*s.*

SUTER No. 2 RAPID APLANAT (No. 13,464).—10½ in. focus; Iris diaphragm (U. S. system No. 2 to No. 100=*f*5.6 to *f*40). Covers ½-plate at full aperture. In good condition. Cost 6*l.* 5*s.*; will sell for 4*l.*

LEREBOUR & SECRETAN (Paris) SINGLE ACHROMATIC LANDSCAPE LENS (No. 4728).—6 in. focus; full aperture, *f*6; one diaphragm, about *f*12; brass cap. Mount scratched and discoloured, but perfect for working. Will sell for 7*s.* 6*d.*

MAX-LEVY CROSS LINE HALF-TONE SCREEN.—7½ in. × 5½ in.; 133 lines per inch. Perfect condition, in original wooden box. Cost 2*l.* 15*s.*; will sell for 2*l.*

May be seen at 6, Farringdon-avenue, London, E.C., or will be sent on approval if inquirer deposits value and pays postage.

\* \* \*

MESSRS. BABAGEE SAKHARAM & Co., of Calcutta, write us: "You are, no doubt, aware that in India there are only three journals which are devoted to further photography either as a science or an art. Whatever may have been the reasons which did not conduce to the rapid growth of photographic journals hitherto, it would be difficult to contend now that a desire to read photographic literature is growing strong. The fact of the new journal at Calcutta securing a good circle of subscribers in so short a time indicates the want that is sorely felt. This need is all the greater on our side of the peninsula, since, of the three Indian journals, two are published in Calcutta and one in Madras. Our position as dealers in photographic goods has prominently brought same to our notice, and created a desire to make an effort at starting a photographic journal. In order to make it sufficiently attractive and popular, it is of prime importance that the subscription should be within the reach of all. Another factor, and by no means inferior, is the quality of the reading matter. The articles must come from the pen of writers who are well known." We understand that Messrs. Sakharam & Co. are desirous of securing the assistance

of some English photographic writers of high reputation. Thus supported, the new journal should have a considerable chance of success.

\* \* \*

IN a recent number of the JOURNAL, *apropos* of the Premo Company, reference was made to the enterprise of American camera-manufacturers in supplying the English market with cheap film cameras, and the inference appeared to be drawn that none of the English manufacturers had so far considered it worth while undertaking the same kind of business. It was, of course, by pure oversight that the fact of Messrs. R. & J. Beck having long held a prominent position in this branch of manufacture was denied reference. The well-known series of Frena film cameras, which range in price from 2*l.* 18*s.* to about thrice that sum, have had a successful career of several years, and the fact that, following the example of *Charley's Aunt*, they are "still running," points to the conclusion that British enterprise, when it is equal to the occasion, is sure to be rewarded by success.

\* \* \*

WE have received from Messrs. R. W. Overton & Co., of 9 and 11, Underbank, Stockport, a copy of Vessière's weather chart for August and September 1899, for the counties of Cumberland, Westmoreland, Lancashire, and Cheshire, also North and South Wales, with North Devon and North Cornwall and the Western Midland Counties. Mr. Vessière observes that "no man has power to foretell the weather of a month hence—with exact precision; but that science has enabled the meteorologist to approach with astonishing nearness admits no doubt." He adds: "The many commendatory letters and allusions we have received from time to time concerning our charts have been somewhat discounted by the different tone of other critics who have found cause for complaint; but, as our experience entirely corroborates that of many highly intelligent and eminent scientists (great authorities on weather), we have not been disposed to feel downcast concerning its incorrectness of principle; we have not scrupled to admit that it is a system which is neither absolute nor faultless, yet one we advise the agriculturalist, out-door operator, tourist, and those responsible for the dates of sporting fixtures and out-door events, to adhere closely to, even if devoid of a normal credulity, as in nine cases out of ten the chart will agree with the daily forecasts issued by the Meteorological Office, and they will be successful in their choice of weather." The cost of the chart is one penny, and, as photographers have as much interest in the weather as most people, some of our readers may care to risk the investment.

#### LENSES FOR LARGE DIRECT PORTRAITURE.

REVERTING to the subject of large direct portraiture—see page 467 of the issue of the 28th ult.—we shall here deal with lenses suitable for that class of work. In the previous article it was mentioned that to obtain portraits with pleasing perspective the equivalent focal length of the lens should be at least double that of the longest dimension of the plate—we say at least, because a longer focal length than that would be still better in the case of large-size portraits. That is because the camera can then be placed at a greater distance from the sitter. This means, of course, that the lens is employed for a much smaller size than its maker constructed it to cover—

though not necessarily to be used for. In the majority of cases in this country, as we have already pointed out, possibly with the view to economy, the lenses are used for the full sizes they are catalogued to cover, and in some instances even larger, with the result that the portraits, by reason of the camera having to be approached very close to the sitter, are very unpleasant, owing to the violence of the perspective, which is often termed distortion, though it is not in reality.

We will now consider the question of lenses suitable for this class of work. As in the former article, we shall quote from the catalogues of our two leading opticians—Ross and Dallmeyer—for the reason that they both contain lenses of similar types, and with, practically, corresponding focal lengths and apertures; also because they seem to be the standards for other opticians' lenses. In the first place we have the portrait lens. Taking one of these of thirty inches focus, we find the price quoted at between 50% and 60%; one of the D or group, and the rapid symmetrical anastigmats, at 45% and 60% respectively. Referring to the list of rapid rectilinears and rapid symmetricals, the prices are about 25%. The first-named lenses have an aperture of  $f-4$ , the second about  $f-6$ , and the last  $f-8$ . Each of these instruments is constructed to cover from  $18 \times 16$  to  $22 \times 20$  inches, but, for the reason we have pointed out, they should not be used for sizes larger than  $15 \times 12$  inches when pleasing results are a consideration.

In the days of the wet-collodion process a lens with a large angular aperture was imperative, owing to the slowness of the process; but now that condition does not obtain, and those with smaller apertures may be used, and yet with much shorter exposures than used to be necessary, so that the portrait lens may, practically, be dismissed from present consideration. Next come the D and the extra-rapid anastigmats, and then the rapid rectilinears, and the rapid symmetricals with their  $f-8$ . Now, if any of the above be stopped down, which is necessary with all of them in order to get the different planes of the picture in fair focus, to the same aperture, the one is just as rapid as the other. Thus if, say, the portrait lens be stopped down to  $f-8$ , all things being equal, it will have no greater rapidity than the rapid rectilinear with its full opening, neither will it possess any greater depth of focus, and, if all of the three series be stopped down further, say  $f-11$ , the conditions will still be the same.

Why, then, it may be asked, pay for an aperture that is of little use in general practice? The only advantage is that the lenses with the larger aperture can be used under adverse conditions, as with a bad light or when photographing children, but then only at the sacrifice of "depth of focus." If, however, these lenses are used for pictures of only half their focal length, they will still cover the plate fairly well without a stop.

In his Presidential address at the late Convention, Mr. Wm. Crooke, referring to lenses, said: "One welcome addition for portraitists would be a lens for studio work that would in some respects resemble the Berghelm in diffusion of focus (too much diffusion would be undesirable), but having sufficient depth to enable focussing to be done roughly, say by measurement, in the studio." Now, do we not already possess a lens that, to an extent, fulfils this condition and have forgotten it? We have in mind the old plano-convex, or slight meniscus landscape lens by Ross and Dallmeyer of fifty years ago. This lens had a fixed stop of somewhere about  $f-15$ , and with that it yielded crisp definition over a tolerably wide area. These lenses are

intended to cover two-thirds of their focal length, and with the above aperture they are as rapid—theoretically more rapid by reason of their having only two reflecting surfaces—than any of the more modern lenses when stopped down to  $f-15$ . If, however, these lenses have their apertures opened out to, say,  $f-11$ , they will still give good definition over a field of half their focal length; and, if opened out still further, say to  $f-8$ , they will still give good *pictorial* definition over that area, such as would satisfy the general public.

It must be borne in mind that excessive sharpness in large portraits, such as results when lenses of the combination form are stopped down to enable them to cover the full sizes they are catalogued to cover, and with sufficient "depth of focus," is offensive to the general public and even to extreme anti-"fuzzyists."

Much of the late Mrs. Julia Cameron's early work was done with a large single landscape lens by Ross, with its fixed stop entirely removed and worked with its full aperture, which then had an aperture of about  $f-5$ ; but, of course, the pictures were of the "fuzziest" of the "fuzzy" order; yet, with the lay press, they tended to make that lady's fame. But, as we have said before, the single lens as turned out by Ross and Dallmeyer in the early sixties will, when the aperture is enlarged to  $f-11$ , or even  $f-8$ , yield excellent large portraits. Some of Mr. V. Blanchard's studies, it may be mentioned, for example, were also taken with a single lens with a very large opening, and this was also in the collodion days. Although the old form of landscape lenses is not made now, Dallmeyer has a long-focus landscape lens with an aperture of about  $f-10$ , and this should be suitable for large portraits. The front lens of the Petzval portrait combination, again, is very similar in character to the old form of landscape lens, and is therefore useful for large portraiture.

We have dealt somewhat fully with the old single lens for portraiture because an impression seems to prevail, even amongst professionals, that a compound lens is an essential, and with some even that a portrait combination is absolutely necessary. The late Mr. J. T. Taylor frequently referred to the suitability of the old single lens, with gelatine plates, for portraiture.

#### COMBINED TONING AND FIXING.

IN speaking of the double salt of hyposulphite, or rather thiosulphate of soda and gold, a casual statement was recently made that this salt formed the active toning agent in what is known as the combined toning and fixing bath. We are well aware that in treating upon this subject we are entering the thorny path of controversy. The actions set up during the process of combined fixing and toning are so obscure and difficult to trace, and the methods by which the results are obtained are so extremely varied, that any attempt to elucidate them would be a task beyond our power. We can only, therefore, speak generally upon the broad principles that are involved. There is, however, a certain simplicity about a combined bath, that is to say, in the use of it, which has a fascination for a very large number both of professional and amateur photographers.

We will at once state that toning is, or should be, a process of substitution, that is to say, that for each atom of gold deposited on the picture a corresponding atom of silver should be eliminated. It is not sufficiently understood, however, that

this is not always the case. In some forms of toning baths, of a somewhat unstable character, the decomposition goes on in the solution itself, and the gold is deposited in a selective manner upon the picture, in a manner analogous to silver intensification of a negative, or to physical development of a wet-collodion plate. In this case a thin coating of gold is deposited upon the surface of the print, and the silver remains behind, and so influences considerably the resulting tone obtained, and also in a large measure the permanency of the image.

A good toning bath should consist of a solution of a salt of gold in a state of unstable equilibrium. The disturbing element is the introduction of the silver print. As we have already pointed out, in ordinary toning baths the gold, in its dissociation from its chlorine, gives up first two atoms to the acetate or phosphate of the bath, and is thus reduced to the sub-chloride or aurous chloride, containing only one chlorine element to one of gold. An interchange at once takes place, and gold is deposited in place of silver, which is formed into silver chloride, to be removed in the fixing bath. Precisely the same thing occurs when the double thiosulphate or sulphocyanide of gold is employed, the silver sodium thiosulphate or sulphocyanide is substituted. If, now, the gold has been made with exact equivalents of hypo and gold, allowing no excess of hypo, then the double silver salt remains insoluble *in situ*, and undoubtedly acts as a further disturbing element, accelerating a further deposition of gold, and toning proceeds uniformly and rapidly, and that by a true substitution process. If, however, there is an excess of hypo present, the soluble double salt is formed, or, more correctly, this insoluble salt is dissolved and instantly removed, and toning is much slower. The greater the excess of hypo, the slower is the gold deposited, or, in other words, the bath is in a very stable condition and no longer parts so readily with its gold. Indeed, we should be disposed to question whether toning by gold ever takes place in a combined fixing and toning bath in such a state of purity as it should be when employed by a conscientious worker.

As against this, many will, no doubt, point out the experience and practice for many years of the thousands who habitually and exclusively employ combined fixing and toning. But here the question comes in, Is it gold toning? We freely admit that with the combined bath beautiful tones are readily obtained, and with an ease and comfort not to be found in the separate toning methods. But that this colour is due to any deposition of gold is exceedingly doubtful, and this is shown by the fact that almost any of these baths will tone equally well if no gold is added to them. When we consider that many of these combined baths in use are made up of a mixture of hypo, gold, lead, citric acid, alum, and other abominations, there is every justification for the belief that sulphur only is the active agent in giving the colour to the prints.

Let any one try the simple experiment of fixing a print, without any previous washing, in a freshly made solution of hypo of the ordinary strength, to which three or four drops only of a solution of sulphate of copper, of the strength of twenty grains to the ounce, has been added. This is a simple combined toning and fixing bath, which will give tones equalling those of the gold bath, but still no copper is deposited or enters into the constitution of the picture.

The tones are entirely due to the complex change which is induced in the hypo solution, accompanied by an elimination of sulphur and sulphur dioxide.

Hypo is one of the most unstable compounds with which the photographer has to deal. The addition of the salt of almost any metal, such as lead, iron, copper, or silver, or of any mineral or organic acid, causes a more or less rapid decomposition accompanied by liberation of sulphur, and sulphur toning is the result. We will take as an example the simplest form of combined bath, that to which a solution of hypo with a certain quantity of a solution of gold chloride is added. On the face of it such a combination is harmless enough; but, as ordinarily made, the acid chloride of gold or auric acid is added, and the same result would have been obtained with hydrochloric used alone without the gold. If the gold were first neutralised and then added to the hypo, or, better still, if the double salt of hyposulphite of gold and soda were first formed separately, and then added to hypo, it would be found that very little toning action took place unless some other disturbing element were introduced. This may be the print itself, just as it comes from the frame and containing considerable quantity of organic salts of silver and free citric or tartaric acids. But here sulphur toning is at once set up, and little if any gold toning accompanies it.

In making these remarks we do not wish to be understood as advocating any special method of toning. Though we believe that the conscientious worker will adhere to the separate toning bath system, yet it does not follow that a sulphur-toned print necessarily fades any more than a gold tone print is of necessity a permanent one. The question of permanence is a relative one, which we prefer not to enter into here. Imperfect fixation causes more fading prints than all other causes combined. If those who prefer to work with sulphur-toning baths, to give them their proper name, would only adopt one or two simple precautions, we should have much less complaint as to the fugitive nature of their productions. All the same, we would prefer to have them called sulphur-toned prints.

---

**Liquid Air.**—It is, in a way, only the other day that liquid air was a great curiosity, a marvel of science, its production being proved by the issue of a mist from a tap when by its turning the pressure was released, and the cold induced by the sudden expansion sufficed to produce minute drops of liquid air, further proof of its having been produced being given by the sound of the drops falling upon a sheet of paper. Now air reduced to the liquid form is produced by the hundreds of gallons, and immense installations of machinery are to be found solely for the production of liquid air. That it will be found to have many uses for photographic purposes is most probable, if even for no other purpose than the marvellous cooling power it possesses. Our contemporary, the *Scientific American*, recently had an illustrated article describing the plant set up by the General Liquid Air and Refrigerating Company for the purpose of producing liquid air, and the extent of the manufacture may be gauged by the size of the huge machines. It is stated that a similar machine, with a possible output of 1500 gallons per day, is being made for Los Angeles, where it will be employed for packing fruit. It may be mentioned that, in connexion with this plant, a receptacle for holding and transporting the liquid air has been devised. It consists of a series of concentric spheres with insulating packing; the expanding liquid forms the atmosphere, passing through the spaces, and so cooling the bulk. The liquid is withdrawn after the manner of a soda-water siphon.

---

**Photographic Researches on Phosphorescent Spectra.**—Under this title Sir William Crookes, F.R.S., recently read before the Royal Society a paper of the highest interest to scientific photographers. The actual object of research, the obtain-

ing pure samples of the new element discovered by him, is foreign to our purpose, but the means employed are of special photographic moment. Sir William found it desirable, in the course of his investigations, to obtain photographs of the invisible ultra-violet spectra of the substance at various stages of its separation, the fiducial lines of this portion of the spectrum being most marked; but, as is well known, these rays do not pass through glass, though quartz is transparent to them. Hence, the whole optical arrangement was composed of the latter material, and was contrived in a most ingenious manner. First is a pair of plano-cylindrical quartz lenses to condense the rays issuing from the incandescent body—*victorium* it is now called; the beam passes through two split right-angled quartz prisms, to be then received upon the sensitive surface. As their focal plane is not flat, but curved, the sensitive surface needs also to be curved to the same extent; this is arranged by using celluloid as a support. The whole arrangement is fully described and illustrated in a recent number of the *Chemical News*.

**Magnesium Flashlights.**—A possibly useful addition to the data governing the composition of these mixtures may be found in a paper recently read before the Paris Academy of Sciences by M. H. le Chatelier, who finds a greater certainty of combustion in mixtures of the nitrate of ammonia class by making a special crystal from a solution containing potassium chlorate and ammonium nitrate. By modifying the temperature of the solution and the proportions of the ingredients, he was able to produce a crystal of definite and constant proportions; it contained five per cent. of the chlorate.

**Splash Preventers.**—When water is taken direct from the main, it very frequently issues from the tap with such force as to be extremely inconvenient, not to say risky, to a negative showing an incipient tendency to frill. We have recently seen a description of a simple little filter attachment for a tap, which is intended to obviate this difficulty, and which is stated to permit the effluent water to issue in an unbroken gentle stream, but with its actual volume undiminished. We have not seen the apparatus in action, but it will very probably be efficient. Our present purpose in writing is to draw attention to the fact that there is a very simple means readily available for subserving the same purpose. No matter how violently water may issue from a tap through pressure at the main, the violence will be quite destroyed if a short piece of indiarubber tubing be slipped over the end of tap. The bore of the tubing will be necessarily larger than that of the tap, and, the issuing column of water having its sectional area increased, the pressure is necessarily, *pro rata*, reduced.

#### CHEAP ADVICE AND CHEAP APPARATUS.

The purchasing power of the modest "brown" has of late years become phenomenal; still it came somewhat as a surprise to find on the book-stalls and in the shops a manual of photography priced at the figure of one penny sterling! There is no doubt, judging from a perusal of its contents, that in a newer, not to say more orthodox and imposing, presentment this little handbook would meet with a ready sale at six times the price, for I may say at once that the advice given, though cheap, is quite free from that common fault usually attributed to goods which are to be had for next to nothing.

I am one of those who agree that the tyro in photographic work cannot too often be impressed with certain general rules and principles; thus, great care in manipulation of apparatus, extreme cleanliness in working, and the exercise of considerable patience are rules fundamental and indispensable to success. What says our penny guide? "It is easy to get good results with very little experience and a limited amount of knowledge, but only with a considerable amount of care." Here is a case in point: two acquaintances of mine, A and B respectively, own a couple of good magazine cameras, identical in structure and capacity. A and B are, photographically, only two months old, but, while A is rapidly accumulating an album full of bright, speaking little bits of local life and colour, B can show scarcely one decent picture! The reason of this falling off is not difficult to discover if you watch B handling his camera in the open; you then say to him that he will never do any good at

photography until he takes a more serious view of the art and practice of picture-taking, masters the intricacies (such as they are) of his apparatus, handles and carries it with reasonable care, and, above all, endeavours to assimilate, if only from books and tables, some general notions of what, in the form of a picture, may be taken with the instrument. Some beginners ought certainly to be put through a course of wet-plate work, a branch of the art which requires a man to handle his tools gingerly if he is to produce any results.

But there is another point: a man will never learn anything of the mysteries of exposure unless he undertakes, in his own person, all the operations of loading the camera, exposing the plates and development of the same, and, finally, of *printing*. How is a man to learn the value of a good negative, to understand what is required of, and meant by, a good negative; or, to put it even more simply, the value of a little more or a trifle less exposure, unless he develops his own exposures and makes his own prints? Think also, for one moment, of what a nuisance this careless man is to his friends, and, above all, to the unfortunate individual who has the development of the exposures—the waste of *time*, and *plates*, and *opportunities*!

When selling cameras (hand cameras, say) the price of the apparatus naturally is an important, perhaps the most important, consideration. We take two cameras, and find that one is ticketed at a guinea, and another at four times that figure, the difference only, leaving out some trifling details, improvements in finish and the like, being that in the higher-priced outfit the lens is a rectilinear. Of course, we take that to be, at first sight, a sufficient reason for the increased charge; but wherein (barring the slightly improved appearance and finish aforesaid) is the one outfit four times the worth of the other? Now, it cannot be denied that the well-made, simple, single lens is a very popular and valuable instrument, valuable out of all proportion to its monetary cost; for pure landscape, some copying, groups, and (in the hands of an expert) certain forms of architecture, this is a lens hard to beat. We say, with some degree of sentiment, that the rectilinear is the best all-round lens, but it is not worth all the extra cost unless it be a lens of undoubted excellence of manufacture; that is to say, if one can only afford a second or third-rate article, the purchaser had better save his money, and for the difference between one and four guineas the lens should bear a name of unquestioned repute. The pre-eminent advantage of a rectilinear lens is the extra rapidity; this, in my opinion, takes precedence (for hand-camera work particularly) of the other points usually credited to this class of lens: flatness of field, freedom from distortion, and so on.

With single lenses of the better class we get wonderful definition, and, if of reasonable focal length, no great amount of distortion; but they often fail us when the light is bad: the tyro expects his apparatus to take "everything," and, if we can start him off with the rectilinear as part of his outfit, we get a step or two nearer the unattainable. Some beginners have a fancy for a wide-angle rectilinear, or, having a wide-angle rectilinear, use it without much discrimination; perhaps it will be safe to merely mention this fact, because wide-angle rectilinears take some studying and manipulation, and errors (the result of their use or misuse) are not always confined to beginners. It comes to this, however, that a great deal may be done in the way of distortion with rectilinears by the otherwise well-meaning but inexperienced operator.

With regard to apparatus, cameras for stand work that is, some good and wholesome advice is given, including that somewhat mystical and questionable axiom, to the effect that if money is a scarcity the cost of the camera should be brought to the lowest figure to the advantage of the lens. One might add, with much truth, that another item which should not be unduly "pinched," is the stand; a rickety stand is of no practical use to anybody. The market is full of shoddy apparatus, most of it fit only for the fire; but, on the other hand, some of this cheap stuff is not at all badly designed—rising front of great range, and nearly square bellows, being notable features, they could be improved further by the addition of a cross front. These cheap outfits are usually fitted with an equally cheap rectilinear (very rarely you may hit upon a really good instrument), which will require a lot of humouring. They can be made to do some fair work, but not without a lot of manœuvring. The cheap professional is a marvel in his affection for shoddy apparatus, and not always from impecuniosity. He will come in and say, "I've made up my mind, Mr. P., to go in for a really good whole-plate set, what do you think of one of So-and-So's," mentioning a well-advertised variety, at 5*l.* 5*s.* complete? This is on a par with the man who, being sent for some good hot-house, fresh, ripe, and luscious grapes, buys some of the imported variety, sawdust included, at 6*d.* per pound. You see one result of the cheap and shoddy in the deplorable series of photographic groups of school children (whole-plate, mounted, price 6*d.*), scattered broadcast

over the country. Such pictures and groups ought to be, and might easily be, made extremely interesting and valuable; as it is, they are for the most part abominations, and reflect anything but credit on the present generation. "Some lenses represent a straight line near the edge of the picture as curved; others (rectilinear) reproduce it correctly." This is so, but with the cheap and shoddy rectilinear you may get something worse than a slight distortion of lines, as witness some of the groups abovesaid.

It is all very well to emphasise this necessity for careful working, but very often our amateur workers fail to have a fair start; there are cameras, arrangements, that is, consisting of dark chamber, lens, and plate-holder, with which no one could do any good. And one is constantly calling attention to the necessity for a rigid stand; a strong, but not necessarily heavy camera made of good and well-seasoned wood, not over-much weighted with showy brass fittings, easy-fitting, well-made slides, true in register and so forth, without making any impression on the steady flow of the "weak-kneed" stuff placed on the market, nor, I fear with little advantage to the consumer, who cannot discover faults until too late, nor estimate their importance until practice and experience have shown him what is or is not desirable in his outfit. On the whole, I think it is of first importance to have a really well-made and designed camera and stand rather than spend the bulk of one's funds on an expensive lens (which on a faulty camera can give little satisfaction). Brilliant work can be done with the comparatively cheap single lens; but there is a consolation also for the user of the cheap rectilinear, let him only study the vagaries of his instrument and he may found a new cult!

J. PIKE.

#### JOTTINGS.

I RENEWED acquaintance with the Gloucester Convention last week in Edinburgh. Such a geographical achievement is, of course, only possible by means of photography, which, in a sense, allows you to emulate the feat of the bird that was said by Sir Boyle Roche to have been in two places at once. To be precise, it was in the Edinburgh establishment of the well-known opticians and apparatus-makers, Messrs. Lizars, that I saw an animated photograph of a large party of Conventioners, taken on one of the excursions, and as I looked at the moving panorama of Convention life and character—there is a great deal of character sharply outlined at a Convention—I seemed, while standing in the Modern Athens, to be living the whole of the Gloucester week over again in the short space of time taken for 150 feet of film to pass through the machine.

Pleasure, it is said, may be divided into two parts: anticipation, retrospection. In the present case they are unequal parts. The pleasures of memory evoked by the Gloucester Convention seem to increase as the days go by. You may be limited by the possibilities of anticipation, but, when you look back upon a particularly happy phase of life that marks itself out from the rest of a humdrum existence, you are apt to find your appreciation of it grow with the distance from which you contemplate it. So it is with the Gloucester Convention. The farther it recedes from view, the brighter and pleasanter it becomes to the mental gaze.

The cinematographic view of the excursion party, which was composed of very well-known figures in the photographic world, led me into this little train of thought. The members are leaving the Severn steamer at Tewkesbury, and in watching how each one, lady or gentleman, young or old, makes across the plank for the shore, you appear to have set before you on the screen the self-revealed character of each person there. Perhaps I speak with special knowledge, as I have the honour of the acquaintance of most of the figures in the picture. However, those who make the matter a special study tell us that character may be read from a person's walk, so that perhaps others, when they come to look upon this animatograph, although the figures are strangers to them, may form a good idea of the traits and foibles of the originals. I do not know, however, that the picture will ever be publicly shown. It is the property, and is in the possession of, the President, Mr. Crooke, for whom it was taken and very well taken, too, by Mr. Paul, of Hatton-garden.

My reference to Edinburgh will tell the reader that I am holiday-making in North Britain; and it is so. I am writing these lines in sight of the Bass Rock and the red-brown jaggedness of the Had-dingtonshire coast, and, for the moment, every prospect pleases. A calm sea is bathed in mellow sunbeams, white fringes of foam kiss the grey and green islets that guard the shore, and the breeze has just so much bite in it as to keep you cool and give you a premature appetite. But the wild and ragged scenery before me is not "photographic," and the hand camera does not appear to be in evidence amongst the visitors to the little town. It is so seldom that I am able to escape photography and the interrogative attentions of those who practise it that I confess to not being sorry at finding myself for a few hours amid absolutely non-photographic surroundings. If I were able to lengthen those hours into weeks or months, I tremble to think of the state of enthusiasm I should be in when I got back to the thralldom of cameraland. It might then be possible for me to grow eloquent over the newest developers. This I take to be enthusiasm in its highest form.

Talking about escaping from photography and photographers, I was thinking I had done so one morning last week, when I was promptly made aware of my error. The 11.30 p.m. "flier" from King's Cross had whisked me down to Edinburgh, and when the sun was well up I started off, invigorated and refreshed, to take my walks among the gaily dressed throngs always to be seen in one of the most picturesque and "gilt-edged" thoroughfares in the world, Princes-street, with which Regent-street, London, is not to be compared. I was just feeling that the sunniness and animation of the scene was sending the roar of the train out of my head and was putting me in trim for a few days' rest with the weight of journalistic liabilities off my shoulders, when right opposite the Scott Monument I was waylaid, captured and held in bondage by a genial Scot, who, before I could realise it, was favouring me with a long and volubly delivered lecture on—not to be too precise—the speed of shutters! Really, I felt inclined to tell Fate that she had played me a very shabby trick indeed. However, even this lecture came to an end at last and I was free to take my dose of Princes-street mentally hoping that I was not destined to pass the whole of a brief vacation in listening to expositions of photographic technology.

Edinburgh's Princes-street photographic establishments vie, in the quality of the work produced there, with the studios of any other thoroughfare in Britain with which I am acquainted. Judging, however, by the specimens that are to be seen, the influence of one man is very conspicuous in its effects upon the work of his *confrères*. Light brown or straw-board mounts of certain sizes and shapes, bearing photographs in a particular shade of sepia carbon or platinum, have for a long time past been associated with the photographic individuality of one particular gentleman whose style of work they are so generally recognised as illustrating, that without the name at the bottom one has hitherto had no difficulty in tracing them to their source. But it was somewhat of a surprise to me to perceive that this gentleman's peculiar characteristics of colour and shapes of mounts, and the tones of his prints are clumsily imitated in several quarters. Surely photography offers such wide scope for individuality, if not originality, of treatment that the need of doing what one's neighbour does is as small as its inadmissibility is great. That photographers should yield to the influence of one among their number who has been successful in importing a highly cultivated individuality into his work is only natural; but that influence, in my humble opinion, should not be allowed to drag those upon whom it reacts down to the comparatively low level of mere imitation.

I took up the pen with the idea to make these a series of holiday jottings, and nothing beyond, and here am I rambling off into the dry fields of ethics. But Edinburgh is a very serious place, of course, and its influence has exerted itself upon me, I suppose. I do not want to send more photographers there than there are at present, but Edinburgh strikes me as being a very good centre indeed for professional photography. In those districts where you get the

higher middle-class men the prosperity of the photographic studios, and the signs of business in course of transaction, appeared to me to be considerable, as I took my rambles round Leith and Newhaven, where the fishwives abound. Edinburgh culture and beauty may not go down that way to be photographed, but there is evidently a large and paying *clientèle* to support Leith's many studios, amongst which I saw no signs of the meanness and squalor that are only too apparent in London and other large towns.

There is a branch of photography the difficulty of which I should think could only be equalled by its fascination—I allude to the portrayal of sporting dogs at work. Last week good fortune and a friend took me to Mornay, among the Lammermoor hills, for the grouse-shooting, and, not carrying a gun, I had every opportunity of studying the ways and manners of the dogs at their work. To do the animals justice by means of photography, doubtless, requires a thorough sportsman to use the camera—men like Mr. W. J. Croall and Mr. Herbert Bowling, whose very fine studies of sporting dogs in the field are triumphs of fidelity and realism, obviously possess expert knowledge of what is required in photography of this kind. Now and again, when the dogs were “pointing,” and the whirr-r-r of the rising birds was followed by the crack, crack of the gun, I was tempted to lament that my camera was not with me; but, not being a “shootist,” I consoled myself with the reflection that, though they might have some photographic merit, my results, if I obtained any, would be more than likely to lack the illustrative points which your sportsman naturally looks for first of all.

Though my charming hostess on the moors smilingly avowed her objection to cameras being used in the shooting box, my companion had his pocket Kodak with him, and had many unique opportunities of using it on the “Twelfth.” His results should prove amusing to look at. It was a blazing hot day among the heather, and some of our costumes, if light and cool, were unsuitable for exhibition in Princes-street, Edinburgh, or Piccadilly, London—pyjama jackets, “slouch” hats—but I need say no more on that head. Not even at the Photographic Convention could such quaint groupings and figure studies be seen. Grouse-shooting (and our party secured sixteen and a half brace, besides many hares, rabbits, snipe, &c.) is a serious as well as an exciting business, and the use of the pocket Kodak served to lighten and diversify the proceedings.

It is the life that I have been leading the last few days—shooting, fishing, golfing, sailing, hill-rambling, and the variegated and undying charm always to be found on large farms, have all been at my disposal—that gives the photographer immense scope for work. It makes one reflect that one's camera should keep company with those little personal *impedimenta* that are never left behind, be always with one in fact. You need nothing larger than a pocket camera for securing the natural and spontaneous groupings and subjects that constantly present themselves to you. They would lose all their naturalness if faced by the very businesslike-looking camera on a tripod. In this respect my companion shows his wisdom. Wherever he goes his pocket Kodak goes with him, and in the four years he has carried it a rich harvest of these nature subjects has fallen to his share. On the whole, I begin to regret having left my hand camera behind. In “escaping” photography this vacation I have thrown away many golden opportunities, opportunities that the town-dwelling photographer sighs in vain for. Decidedly I must unsway what I have said. Photography and the camera should be always with you.

Bidding adieu to the gracious lady of Lammermoor and my hearty host, hand grips are exchanged, and, with a last look at the dogs, the horses, the cows, the trout stream in the valley, and the heather-clad moors, we are driven away from the Ravenswood country in the early morning. By nine I am on the Haddingtonshire rocks, seated at my table on the verandah which overlooks the

German Ocean. The post has brought me three parcels of letters, papers, photographs, &c. In a few minutes the pen is in my hand again; my kindly hosts and hostesses leave me to myself, and, though the murmurs of the waves are in my ears, the soft breezes fanning my rapidly browning face, and the hot sun is driving the sea fog off the surface of the blue-green wastes at my feet, moorland and sea are quite forgotten, and the pen, as it journeys across my writing book, carries me, for a while, three or four hundred miles away, and my heart and mind are in the world of photography once more.

COSMOS.

## THE RAPIDITY OF DEVELOPMENT.

[Translated from Dr. J. M. Eder's *Jahrbuch für Photographie*.]

IN the development of a gelatino-bromide plate the exposed silver bromide is converted to metallic silver by a solution that effects reduction. The blackening of the photographic film in consequence of this reduction will take place more rapidly in proportion to the intensity of the light and the length of exposure. The development of a plate exposed in the camera is therefore progressive. Reduction begins at those parts corresponding to the highest lights, and gradually extends till finally metallic silver is also reduced from those particles of silver bromide which have been but slightly affected by light. At this stage the progress of development is stopped. The time occupied by the process is called the “duration of development,” and its reciprocal expression “rapidity of development.”

The progressive course of the phenomenon of development may be explained in the following manner. The molecules of the reducing substance which the developing solution contains are in a different condition of motion, and this gives rise to differences in their reactive power. The fully exposed silver bromide is affected by molecules with only slight reactive capacity, whilst those particles which have had little exposure to light are only amenable to the impact of molecules of great reactive capacity.

As every part of the silver bromide film is subjected to the influence of the same number of molecules of developer in the same unit of time, and as nearly all have the power of reducing fully exposed silver bromide, whilst but few have the capacity of decomposing the slightly exposed silver salt, it follows that the first signs of reduction or darkening of the film must be shown by the former.

The explanation of the progressive course of every chemical reaction may be similarly regarded, and the rapidity of development of the photographic plate must consequently depend upon those laws which govern every chemical process. The first deduction we may make from this conclusion is the fact that the quantity of developing solution does not affect the duration of development, because the insoluble silver bromide and the solution form a heterogeneous system.

The chemical peculiarities of the reducing substance and the concentration and temperature of the solution must also influence the rapidity of development. Certain substances may also affect the duration of development in the same way that the presence of foreign substances may retard or accelerate any chemical reaction. We propose examining these conditions rather more thoroughly in the following remarks.

**A. The Chemical Peculiarities of Developers.**—The various substances which serve as developers in the processes of reduction vary in the intensity of their chemical power, and this may be described as their “strength.” The expression is used, for instance, in relation to acids and is a measure of their affinity to bases. We speak of sulphuric acid as “stronger” than acetic acid, and the expression may be applied in the same way to amidol as compared with hydroquinone. The “strength” of the developer must be distinguished from its “power of reduction.” Dr. M. Andresen recently made a very interesting communication concerning the latter (*Photographisches Correspondenz* 1898, p. 447).

The quantity of silver bromide reduced by a definite quantity of developer is a measure of its “power of reduction” or “reductive value.” The “reductive value” and “strength” of a developer are therefore expressions which resemble the “equivalent” and “strength” of an acid or a base, and, whilst the “reductive value” principally affects the density of the negative, the “strength” governs the rapidity of the development.

Nothing whatever is yet known of the connexion between the chemical constitution and the strength of a developer. In practice we speak of rapid and slow developers, and, by comparing the time of development under similar conditions, numerical expressions may be formulated to indicate the strength of the developer. If, for instance, we take 100 as

expressing the rapidity of development with amidol, we arrive at 25 and 93 as the numbers for glycin and hydroquinone, under similar conditions.

The strength of the alkaline developers depends largely upon their more or less alkaline condition. If it is desired to arrive at the same rapidity with a developer by using different alkalies, their quantity must be determined by assimilating their same alkaline condition. For instance, if we wish to obtain the effect of 10 grammes of potash by substituting caustic soda, the equivalent quantity of the latter (5.8 grammes) should not be used, but preferably a much less quantity, because caustic soda is a much stronger alkali. We find, by experiment, that about 1 gramme of caustic soda is sufficient to produce the same rapidity as 10 grammes of potash.

If the quantity of alkali in the developer is progressively increased, the rapidity increases also. This is at first very marked, whilst further additions tend to a definite maximum. The accession of rapidity follows the same law as that which governs the alkalinity of the solution in its progressive concentration. The alkalinity is proportional to the electric conductivity of the solution, and experiment actually shows that the rapidity of development is inversely proportional to the electrical resistance of an aqueous alkaline solution of the same concentration.

**B. The Concentration of the Developer.**—By diluting an alkaline developer, the rapidity of development falls in proportion to the reduction of alkalinity. The rapidity of a developer diluted with two, three, or four times the quantity of water, is therefore proportional to the electric conductivity of an alkaline solution similarly diluted two, three, or four times. The decrease in rapidity of an iron developer follows a precisely similar law. In this case the reducer is ferric oxalate, and the power of reaction possessed by the solution is proportional to its electric conductivity, as may be seen from the following figures:—

Ferric Oxalate.	Electrical Resistance.	Time of Development.
3 per cent.	24	20 seconds.
2    "	28	29    "
1    "	45	47    "
0.5   "	90	85    "

For facility of comparison the electrical resistance is expressed in arbitrary units.

**C. The Temperature of the Developer.**—Temperature has great influence upon the rapidity of development, and the accelerating effect of heat in developing the photographic image is well known. The time of development diminishes somewhat uniformly with the increase of temperature, within certain limits, as may be seen from the following experiments:—

	Temperature.	Time of Development.
Glycin	12°	138
	17°	104
	22°	60
Amidol	0°	70
	8°	48
	16°	22

By varying the temperature we have an excellent means of altering the rapidity of development without changing the constituents of the developer. If, for example, we reduce the temperature of an amidol developer to 0°, it works with about the same rapidity as glycin-potash at 22° or diogen at 16°. The common opinion that slow developers, such as hydroquinone, lose their power entirely at 0° is not a fact. Hydroquinone at 0° is only about two or three times slower than at 18°.

**D. The Influence of Foreign Substances in the Developer.**—The best-known means, and that most commonly used, for due regulation of the rapidity of development, is the addition of soluble bromides. Their action may be explained by the creation of a tendency to reconstitute bromide of silver. The reductive strength of the developer is thus weakened, and the rapidity of the process of reduction retarded.

These conditions are most apparent in development with oxalate of iron, in which case the potassium ferrous oxalate and silver bromide are converted to ferric oxalate, bromide of potassium, and metallic silver. The three last-named substances have the power to react upon each other and form silver bromide, and consequently cause a tendency to reverse action in the developer. The greater the quantity of ferric oxalate and potassium bromide present in the developer, the slower is the process of development, and, if the quantity reaches sufficient proportions, development is arrested. If either of these ingredients is increased, the intensity of the reverse process will be raised, and it therefore follows that the addition of potassium bromide or ferric oxalate

will retard the rapidity of development. It of course follows that the addition of similar chemical substances must have a like effect, according to their respective affinities. Consequently all the ferric salts, and likewise the chlorides and iodides, act as restrainers.

In the case of the alkaline developers the process cannot be reversed straight away in the manner we have just described, but a tendency to the reconstitution of silver bromide is produced in the course of development by formation of the products of decomposition. The efficiency of the addition of bromide to these developers is therefore lower, and depends upon the chemical activity of the other products of decomposition.

These views explain numerous facts which have been found empirically. Chlorides restrain very little, whilst iodides have very considerable retarding influence upon the developer, because chlorine has little, and iodine great, affinity for silver. Bromide of ammonium has more restraining power than the equivalent quantity of bromide of potassium, because bromine has less affinity for the former. A developer which has been used frequently is slower, because it contains more products of decomposition, and so on.

The restraining action of apparently indifferent substances may also be easily explained upon the ground of our previous inquiries. Glycerine, sugar, salts, organic acids, borax, &c., were known to have restraining properties, but no explanation could be given for the same; but, if the influence of such additions upon the electric conductivity of alkaline solutions is examined, it will be found that they always impede it. The resistance of a one per cent. solution of potash is approximately doubled by the addition of ten per cent. of glycerine or sugar. Probably combinations having the nature of salts, with low power of dissociation, are formed. Such additions consequently diminish the alkalinity of the developer, and at the same time lower the rapidity of the process of reduction.

The salts of the organic acids, as for instance the citrates, have great influence upon the rapidity of pyro development. As such acids are always formed during the oxidation of alkaline pyro, it is possible that their presence in the developer has the same effect as that of the products of decomposition, and retards the rapidity of development for similar reasons.

BARON ARTHUR VON HÜBL.

## COMBINED DEVELOPMENT AND FIXATION.

[Translated from the *Photographische Correspondenz*.]

PUNNETT pointed out that chloro-bromide plates could be simultaneously developed and fixed (see THE BRITISH JOURNAL OF PHOTOGRAPHY, 1898, p. 126). Hanneke has also written concerning similar experiments with bromide plates in the *Photographische Mittheilungen*, 1899, p. 141. The developing power of alkaline pyrocatechin upon bromide of silver is very little affected by hyposulphite of soda, and the quantity of the latter may be so far increased in relation to the former that development and fixation with a single solution may be effected in a few minutes. Theoretically the matter is very interesting. But efforts are now being made, in Germany, I believe, to apply it practically, and under the name of "Elconal F," a strong, concentrated, fixing developer has been placed upon the market and sold in Vienna. Messrs. Ellon & Co. have patented the process, but grant the right to use it to each purchaser of Ellon's pyrocatechin. The formula is as follows:—

No. 1.	
Water .....	250 c. c.
Hypsulphite of soda.....	50 grammes.
No. 2.	
Water .....	75 c. c.
Sulphite of soda .....	30 grammes.
Caustic potash (pure—in sticks) .....	7    "
Pyrocatechin .....	7    "

For developing and fixing a normal plate 18×18 c., take 12 c. c. of developer No. 1, 20 c. c. of fixing solution No. 2, and 30 c. c. of water. The processes of development and fixation are simultaneous. We mention this novelty, as in some quarters it is spoken of as a great advance in photographic development.

In our opinion the new method is very questionable. It is well known that the duration of development must depend upon the exposure, the lighting, and the nature of the subject; also that the temperature of the developer and many other subsidiary circumstances play a part. The fixing process proceeds independently, but the rapid interruption, or the prolongation of the development process, which are such important

factor for the success of a fine negative in the hands of a competent photographer, become an impossibility.

It seems superfluous to demonstrate further to the professional photographer that combined development and fixation cannot be regarded as an advance, and that it is not destined to replace the separate development and fixing processes in applied photography. DR. J. M. EDER.

### THE NASCENT SILVER THEORY ONCE MORE!

(Translated from the *Photographische Correspondenz*.)

THE view that the latent photographic image is due to the formation of nascent silver immediate upon exposure is becoming still more untenable. After the appearance of my two articles containing the arguments against the correctness of the "Nascent Silver Theory," other photographic chemists took up the controversy. Herr Karl Schaum was unable to discover any distinct traces of reduction due to the contact of metallic silver and silver bromide; but, in the case of finely divided metallic silver (Abney's experiment) a slight action of nascent silver is perceptible. I have always considered this reaction as merely subsidiary in the case of silver bromide plates, and at present I am disposed to give it still more subsidiary importance in the production of the developable image. There is, consequently, no contradiction in my views concerning this process, and I agree with Schaum that the production of the negative by development is due to the action of the chemically active rays. As recent experiments have shown, these penetrate thick films of bromide emulsion to a comparatively exceptional extent. My assertion remains unrefuted, that, whatever the substance may be of which the latent primary photographic image is composed, it is quite certain that it cannot be metallic silver, as required by Professor Abegg's nascent silver theory. Moreover, the experiments which Dr. V. Schumann has recently made with gelatino-bromide plates prove that in this case nitric acid does not destroy the image, which I have also proved with collodio-bromide.

"This fact proves conclusively that the latent image formed in gelatino-silver bromide cannot consist of metallic silver."

The contention between me, on the one hand, and Professor Abegg and Dr. Englisch on the other, concerns this point only. The contention has nothing whatever to do with the extent to which contact between metallic silver and silver bromide may influence in a subsidiary way the primary latent image under the action of the developer. The question is clearly and distinctly—

1. Does the primary latent image consist of metallic silver (the nascent silver theory of Professor Abegg and Dr. Englisch, which I hold to be false), or,

2. Does it consist of anything else, viz., silver sub-bromide (the theory which I hold)?

The subhaloid theory is that which I accept and have proved experimentally. It was for Dr. Englisch to prove the contrary. In relation to both these theories, I discussed in my last article the improbability of the theory of molecular transformation of the molecule of silver bromide. As opposed to this, I cited the experiment by which the latent image was destroyed by bromine. I grant that it is possible to harmonise the nascent silver theory with this experiment, but this is out of the question, as it is upset by the nitric acid experiment. It is therefore an oversight on the part of Dr. Englisch if he thinks that the bromine experiment was brought forward "to save the subhaloid theory." The bromine experiment is inapplicable to it, but at the same time it is not contradictory. The sub haloid theory is not, however, in need of rescue, as it does not yet stand in any danger of the untenable nascent silver theory.

The support of the silver haloid theory is the nitric acid experiment, and this has not been weakened by any of the followers of the nascent silver theory. Neither have they sought so to do, which is the only means by which the latter theory could be saved. The subhaloid theory is founded upon experiment, it agrees best with all observed phenomena, and the defenders of the nascent silver theory who oppose it cannot say the same of that for which they are contending.

DR. J. M. EDER.

### ON THE ACTION OF LIGHT ON THE SALTS OF COBALT.

#### PART VI. EXPERIMENTS WITH COBALTIC MOLYBDATE.

COBALTIC hydrate, even when in a freshly precipitated state, seems to be incapable of combining directly with molybdic trioxide to form a soluble molybdate. On boiling a mixture of the hydrate and trioxide in the requisite combining proportions in the presence of water, the former exchanged its deep brown colour for a dingy reddish-yellow, and assumed

a more flocculent form. After allowing the insoluble matter to subside, paper was coated with the supernatant liquid, dried in the dark, and exposed under a negative as usual. Seventy-five hours' printing in a good light failed to produce an image, whilst treatment in the ferricyanide bath afforded no more successful result. These facts were taken to indicate that no molybdate, or, at all events, no more than a trace of such, was present in the paper—a conclusion confirmed by subsequent inquiry.

It was accordingly found necessary to prepare the molybdate by double decomposition. For this purpose the following process was resorted to: An aqueous solution of cobaltic tartrate, slightly acidified with tartaric acid, was mixed with one of potassium molybdate, and the mixture, after being well stirred, was allowed to stand for a few hours to permit of the sparingly soluble potassium hydrogen tartrate separating out. The clear solution of the cobaltic salt was then decanted off, and paper sensitised therewith and dried in the dark. On exposing a strip of this paper under the solar spectrum for thirty hours, a distinct band of a pure yellow colour was impressed by the yellow rays, but all rays of a greater or less degree of refrangibility than the yellow seemed to possess no actinic influence, as beneath them the remaining portions of the strip retained their original white colour. A moderate increase in the duration of the exposure served to intensify the depth of the yellow colour. An excess of exposure seemed to be productive of a bleaching or secondary action. The latter, however, was of a very feeble character, as may be judged from the circumstance that, after considerably more than 100 hours had elapsed, the yellow band was still perfectly distinct. In the course of a few hours more the strip was removed and transferred to a bath containing a weak aqueous solution of argentic nitrate.

The yellow band was gradually bleached, and, in a short time, entirely destroyed, the strip now appearing in its original whiteness throughout its entire length. A second strip of the sensitive paper was next exposed in the spectrum slide for forty-five hours, by which time the yellow band had attained pretty nearly its maximum intensity. On developing this print in the usual aqueous ferricyanide bath, a new image of feeble intensity and purple-red colour revealed itself, the details of which, in so far as they were found to lend themselves to reproduction, are represented

FIG. 18.—COBALTIC MOLYBDATE.

in fig. 18. The predominant influence exercised by the blue rays, extending with slightly diminished power into the region of the green, is here very noticeable. So, too, is the comparatively strong action due to the orange, and the absence of any action in the yellow rays. With reference to the latter, the attention of photographers is called to the fact that the molybdate, like the hypothetical chlorobenzoate described in the previous article, is sensitive to two groups of selected rays, the one set producing the visible and the other the latent or invisible image. What is still more remarkable is that in both the instances cited we find that the rays of each group are apparently mutually exclusive, no single group of rays being common to both groups. To take the case of the molybdate, the primary image, i.e., that due to "printing out," is due to the yellow rays, and all rays but the yellow are without photographic action.

Conversely, the latent image formed simultaneously with the visible yellow band is, in its turn, due to the impact of all the rays of the spectrum except the yellow, the latter having apparently been deprived of further chemical power on bringing about the molecular transformation, of which the visible image is the tangible result.

Did space permit, a curious parallel might be established between these results and certain closely related phenomena, partly optical, partly chemical in character, of which the various investigations dealing with the reversal of the Fraunhofer lines of the solar spectrum, and Bunsen's classical researches on the relations existing between the emissive and absorption spectra of the salts of didymium and the so-called erbium, afford instances that will readily be recalled by students of science. Apart from its bearings on matters of theory, the circumstance that the yellow rays of the spectrum act on cobaltic molybdate to produce a yellow-coloured compound is interesting in view of the purpose which this property might be made to serve in heliochromic photography. Were it possible by any means to increase the sensitivity of the molybdate to luminous action, the selective property of the salt might be utilised in the camera as a means of producing a yellow image, due solely to the yellow wave-lengths of the object to be depicted.

The chemical composition of this yellow body has not been ascertained. It seems improbable that it is cobaltous molybdate, for when a cobaltous salt is treated with a solution of potassium or sodium molybdate, though

at first no precipitate is produced, upon allowing the mixture to stand for a few hours, what would appear to be the compound in question is deposited in the form of an amorphous violet-coloured mass.

#### EXPERIMENTS WITH COBALTIC PERSULPHOMOLYBDATE.

A solution of potassium persulphomolybdate was prepared by passing sulphuretted hydrogen through an aqueous solution of potassium molybdate. After filtering, a portion of the clear crimson solution was added to an equal volume of a solution of the requisite quantity of acidified cobaltic tartrate, and the mixture was stirred and allowed to stand until quite clear. Paper was then sensitised with the cobaltic salt thus formed and dried in the dark. It should be added that during the preparation of this compound a small quantity of sulphide of cobalt was also formed, due to the action on the tartrate of a little free sulphuretted hydrogen obstinately retained by the solution after saturation with the gas. The sensitised paper, which was of a vivid dried yellow-brown colour, was duly exposed under a negative in sunlight, and in the course of three hours a positive image in faint outline was just perceptible, the hue inclining to an orange or orange-brown. A second sheet was exposed in the spectrum slide for a similar period. The resulting image was exceedingly weak, and seemed to be due to the green, the red, the orange, and the yellow rays, the first-named having impressed themselves with the greatest force, whilst the minimum point seemed to be situated about midway between the maximum point and the end of visible red. The spectrum slide was then replaced in the camera, and the print again exposed to light. Little change, however, was produced, and none in the direction of a gain in the intensity of the deposit, the image, after an exposure of seventy-five hours in all, being decidedly weaker than when first examined. The strip was next divided longitudinally into two parts, one of which was then treated in the ferriyanide bath, and the other in a bath containing a weak solution of argentic nitrate. No alteration was effected in the appearance of the image in the case of the former.

In the nitrate bath, however, a rich deep brown image was obtained in the course of a few seconds. A careful scrutiny of the print after development revealed the fact that the silver solution had acted simply

FIG. 19.—COBALTIC PERSULPHOMOLYBDATE.

as an intensifier, the outlines of the colour bands and their relative intensities being coincident with those of the visible image. Fig. 19 gives a fair idea of the character of this spectrum. It is curious to note that the chemical action is practically confined to the less refrangible end, the outward boundaries of the green region marking its limits.

#### EXPERIMENTS WITH COBALTIC ARSENIATE.

This salt was prepared by double decomposition by the addition of a solution of potassium arseniate to one of cobaltic oxalate. The sensitised paper, after drying, was of a greenish-yellow colour. One of the sheets was exposed to light under a negative, and another in the spectrum slide.

These were examined from time to time during the course of the exposure, but on neither could any signs of an image be traced. At the expiry of seventy-five hours they were removed, divided into two parts, and a pair of odd halves were then transferred to the usual ferriyanide bath. The process of tentative development lasted about thirty minutes, but no image resulted in either case, nor was there any change in the appearance of the paper indicative of chemical action.

The remaining halves were in turn developed in a second bath containing a very weak solution of argentic nitrate. Both during and after development the deposit of argentic arseniate formed by the action of the bath was very carefully examined, but not the slightest indication of an image could be detected on either, the red precipitate being distributed over the surface of the paper with perfect uniformity.

These experiments would seem to indicate that cobaltic arseniate is not sensitive to the action of light.

Confirmatory evidence is, however, required to decide this point, and the subject merits further investigation.

#### EXPERIMENTS WITH COBALTIC ARSENITE.

Some freshly precipitated cobaltic hydrate was placed in a test tube containing water and arsenious oxide. On boiling the mixture, a solution was obtained, though with some difficulty, as the hydrate dissolved very slowly, leaving a residue which resisted further action and had to be filtered off. Paper was coated with the filtrate, dried, and exposed

under a negative in sunlight. After three hours had expired, the high lights of the picture were just rendered perceptible, being outlined in unchanged white upon a pale yellow ground. On increasing the exposure, little change was at first apparent, but afterwards a bleaching action set in, and in from seventy to seventy-five hours from the beginning of the printing process the image had quite disappeared. An attempt was then made to revive it by development in the ferriyanide bath, but this was not attended with success. A second portion of the sensitised paper was next exposed to light in the spectrum slide. In three hours' time a faint but perfectly distinct band was visible under the yellow rays, and there were also indications of bands in the red and the orange, these latter being, however, of a more dubious character. On increasing the exposure, the bleaching action again supervened, and the image, after the lapse of seventy-five hours, was, as before, rendered invisible. On removing the print from the camera, it was immersed in the very weak silver bath employed in the experiments with the arseniate. After a lengthy development, the band marking the position of the yellow rays was restored to view, but nothing could be seen of the bands due to the action of the red and the orange rays.

It was noted, too, that the visible band was fainter than when first seen, and also that it had undergone a transformation in hue from yellow to orange.

#### EXPERIMENTS WITH COBALTIC ORTHOPHOSPHATE.

Paper was sensitised by coating with a solution of cobaltic citrate to which the necessary proportion of a soluble phosphate had been added, the salt chosen for this purpose being disodic orthophosphate. A portion of the dried paper was exposed in sunshine under a negative. Though the printing process was unusually protracted, not the slightest trace of an image could be perceived at any stage of the operation. A second sheet, however, which had been exposed to the rays of the spectrum for only three hours, gave an image of feeble character and purple colour by development when treated in a ferriyanide bath, acidified with a few drops of weak acetic acid.

This image is graphically represented in fig. 20. The action here is

FIG. 20.—COBALTIC ORTHOPHOSPHATE.

due mainly to the blue and the orange rays, the rays of an intermediate order of refrangibility exercising hardly any chemical influence.

In the next experiment a portion of the paper was exposed for twenty-five hours to the rays of the spectrum.

No visible impression having been produced, the sheet was divided into two parts, one of which was then immersed in an aqueous solution of mercurous nitrate. This treatment, however, occasioned no change in the appearance of the print, nor did the subsequent addition of a solution of lead nitrate to the bath act as a developer of the latent image.

The other half was treated in the usual neutral ferriyanide bath.

The result was fairly satisfactory, a strong impression of a band marking the position of the green rays of the spectrum being obtained without difficulty. No certain indications of action due to the other rays could be perceived, but the strip throughout its length was uniformly tinted a very delicate sea green. On acidifying the bath with acetic acid, the band in the green was destroyed, the paper being bleached. In the fourth experiment, after an exposure of thirty hours in the spectrum slide a solution of lead nitrate made slightly alkaline with ammonia was employed as a developer. No change being perceptible, the print was rinsed in water and transferred to a very weak solution of potassium bichromate. The yellow precipitate of chromate of lead now formed was very carefully examined, but there was an entire absence of markings that could be attributed to the action of the spectrum.

An increase of five hours having been made in the exposure of the next sheet, the print was developed in a neutral bath of potassium ferriyanide. The strip was speedily dyed a purple-red from end to end, the depth and intensity of the colour deposit being apparently the same at all points of the spectrum band.

A sixth sheet, exposed to the light of the spectrum for fifty hours, on being treated in the same way, afforded a similar result, the purple colour due to the change effected by the active radiations being now, however, considerably intensified. These results lead us to the important and unexpected conclusion that the orthophosphate, when first exposed to light, is sensitive to a few definite isolated groups of wave-lengths, by the continued impact of which it is slowly decomposed. When, however, the exposure reaches a certain point, the decomposition is greatly accelerated, the change being now no longer effected by a mere selection of wave-lengths, but by every ray of the spectrum alike, the upshot of which is, of course, the production of the same intensity of chemical action at each point where there is luminiferous impact.

Two experiments made with this salt belonging to a slightly different category may be briefly noticed. The first was made by wetting a sheet of the sensitised paper with a weak solution of sodium carbonate rendered strongly alkaline with ammonia. On exposing this in a damp state for one hour in sunlight under a negative, an exceedingly weak outline in purple of the brighter portions of the picture was obtained. The deposit forming this image was very similar in appearance and properties to that of cobaltous orthophosphate as precipitated from a soluble cobaltous salt, and it is not unlikely that it may have consisted of a mixture of that compound with cobaltous carbonate and hydrate.

In the second experiment the sensitised paper was coated with a weak solution of potassium dichromate, and, after drying, exposed to light under a negative for twenty hours.

No image was obtained, but the yellow colour due to the dichromate was gradually bleached, the paper ultimately becoming perfectly white. A ferrous-oxalate developer was then applied, but no visible change ensued beyond a slight darkening, which was clearly attributable to the action of the iron compound upon the phosphate.

#### EXPERIMENTS WITH COBALTIC PYROPHOSPHATE.

A sensitising bath was prepared by double decomposition, the salts employed for the purpose being sodium pyrophosphate and cobaltic citrate. A sensitised sheet, after drying, was exposed to the rays of the spectrum for three hours.

On development in the ferricyanide bath a very delicate tint was produced, the uniform character of which seemed to show that the change effected was not due to the action of light. The next sheet, on being exposed for twenty-five hours, was divided into two parts, and the first half developed in the mercurous nitrate bath, lead nitrate being again added during the course of the operations. As in the case of the orthophosphate, no image was produced. The remaining half was then immersed in the ferricyanide bath. After a few minutes had elapsed, indications which were presumed to be due to an image made their appearance, but so exceedingly faint were they that no certain conclusion could be drawn. On acidifying the bath with a little acetic acid they entirely disappeared. A third sheet, which had meanwhile been exposed in the spectrum slide for thirty hours or thereby, was developed in the lead nitrate bath, and afterwards treated with a weak solution of potassium dichromate. Neither of these operations revealed any action that could with probability be held to show that development had taken place.

In the fourth experiment a neutral ferricyanide solution was substituted for the lead bath, and on immersing the print (which had received an exposure of thirty-five hours) a pink deposit was again produced very similar in character to that obtained in the first experiment, the depth of colour being in no wise greater.

Finally, a sheet of the sensitised paper was exposed to the spectral action for fifty to sixty hours. On being removed to the ferri-

ngly, a quantity of freshly precipitated cobaltic hydrate was digested for several days in a moderately strong solution of metaphosphoric acid. As a safeguard against the formation of orthophosphoric acid, no heat whatever was applied during the process of digestion. After filtering off the insoluble residue, paper was coated with the pink solution, dried in the dark, and exposed to the action of the spectrum. When forty-five hours had elapsed, it was removed from the slide, no image being then perceptible, and immersed in the ferricyanide bath. A rather feeble purple-red image resulted, the details of which it has been attempted to reproduce

FIG. 22.—COBALTIC METAPHOSPHATE.

in fig. 22. In the print itself the relative intensities of the rays at the more refrangible end could be determined without difficulty, but at the opposite end the red deposit was too slight to permit of more than an approximation being made as to the influence exercised by the rays lying in that quarter. The fact, however, was evident that the maximum action was due to the blue rays, beyond which a slight diminution of intensity was noticeable in the region of the indigo rays, and a corresponding increase in that of the violet.

In sensitiveness to light the metaphosphate would seem to occupy an intermediate position in the group to which it belongs, being less sensitive than the orthophosphate but more so than the pyrophosphate.

#### PRINTING DRAWINGS BY MEANS OF PHOTOGRAPHY.

HERR AUGUST SCHWABZ points out that the difficulty attendant upon the use of artificial light for the purpose of the production of photographic prints of large drawings is that the rays do not run parallel as is the case with sunlight, but proceed radially from a point, and in consequence the surface of the sensitised paper or film is not regularly illuminated. The employment of reflectors to obviate this difficulty is only possible for

FIG. 21.—COBALTIC PYROPHOSPHATE.

cyanide bath, an immersion of a few seconds sufficed to develop a vigorous purple or plum-coloured image, exhibiting the series of bands shown in fig. 21.

As a confirmatory test, a second sheet was exposed in the slide for a like period and developed in the same solution. The resulting print was in all respects similar to the foregoing. The action, as will be seen by referring to the diagram, is most powerful in the region of the indigo rays. The violet rays, however, are potent in a less degree, whilst the blue rays, and even the yellow, are not without a slight share of influence.

On the whole, the evidence tends to show that the pyrophosphate is considerably less sensitive to light than the orthophosphate. Judging from the results of the first and fourth of these experiments, it would also seem probable that it is one of that class of inorganic cobaltic salts already alluded to, the members of which undergo gradual decomposition, not only in the light but also in perfect darkness.

#### EXPERIMENTS WITH COBALTIC METAPHOSPHATE.

An attempt was at first made to prepare this salt by double decomposition, paper being treated with successive washes of solution of cobaltic oxalate and potassium metaphosphate. After drying, two sheets were exposed in succession, the one to the action of the spectrum and the other beneath a negative in diffused daylight, the exposure in each case being forty hours. In neither case was a visible image produced, nor was any latent image developed when the prints were treated in a neutral ferricyanide bath.

It was then decided to prepare the metaphosphate directly. Accord-

small surfaces, as the source of light must be as near as possible to the sensitised paper or film. Consequently, nothing further remains for the production of larger copies than the arrangement closely together of a great number of lights, which, of course, has the disadvantage of too great expense.

His invention consists in the employment of an open shell of any shape, having its interior enamelled a dull white, and having its interior approximately of the same size as the drawing to be copied, and the

arrangement within such shell of a number of sources of light close to the interior face of the shell, and the arrangement of the copying frame in front of the open part of the shell. The interior of the shell is regularly illuminated by means of the lights, and reflects light equally upon all parts of the copying frame.

The shell, *a*, is enamelled or painted dull white within, and is constructed with its respective faces of one sheet of metal, or, as illustrated, it may be constructed of several metal plates, which may be riveted or otherwise secured together to form a staunch construction. Lights, *b*, indicated by crosses, are arranged in proximity to the rear interior face of the shell, and these may be arc lamps, incandescent electric lamps, or mantles, or acetylene gas flames, or other source of light. *d* (fig. 2) is the copying frame, in which is mounted a glass plate, *c*, behind which the drawing and sensitised paper or film are held by means of a felt padded wooden plate, *f*, pressed home by means of transverse bars, *g*. The distance, *e*, between the shell and the copying frame, prevents the undue heating of the glass plate, *c*, and serves for the purpose of observation. The shell and copying frame may be mounted, one in relation to the other, as may be convenient.

### CAMERA FOR THREE-COLOUR WORK.

MR. WALTER WHITE has patented an improved camera for three-colour work:—

He says: "I so construct a camera, or apparatus, that it shall have means of adjustment suitable for employing according to the height or direction of the source of light and the position of the observer's eye when the apparatus is used as a viewing instrument, the said apparatus being also easily convertible into a camera for producing the three negatives simultaneously. When used as a camera, an improved arrangement for focussing is employed, and the use of lenses of shorter focus than it has hitherto been possible to make use of is rendered practicable. The colour screens employed for negative-making may be

employed for viewing, with the aid of an additional screen to control them.

"The apparatus consists of a casing or body, *A*, constructed to carry three sensitive plates or transparencies, and containing two transparent mirrors, *B* and *C*, at an angle of  $90^\circ$  to each other, so disposed as to reflect images upon two sensitive plates, or from two transparencies, placed at the upper and lower sides of such casing, each mirror being at an angle of  $45^\circ$  to the focal plane, or third plate, or transparency.

"For the production of negatives, the apparatus is fitted with a lens, *D*, as for ordinary photography. A bellows front, *E*, is attached to the casing by a frame, *F*, carrying such bellows, arranged to fit in position, and held in place by turn buttons or other suitable means. This frame

carries a pinion, *G*, projecting horizontally beyond the two sides of the casing. The frame, *H*, at the opposite or front end of bellows, carries at each side a length of rack, *J*, which rests upon and is worked by the pinion affixed to the back frame. The rack moves under a guide, *K*, or between two guides affixed to each side of the casing. A piece of single or double angle metal forms a suitable guide.

"In the opening of the front frame of bellows is inserted a box or chamber, *L*, preferably constructed of thin metal and open at the front. This occupies the space in the interior of the bellows, and carries at the back the lens that is to be employed.

"The transparent mirrors contained in the body of the apparatus may be of yellow or orange or red glass. The first mirror, *B*, or that nearest the lens, may be of yellow glass, and reflects an image downwards upon a sensitive plate at the bottom of the casing. The second mirror, *C*, may be of orange or red glass, and reflects an image upwards upon a second sensitive plate at the top of the casing. The third sensitive plate at the back or end of the apparatus, as in ordinary photography, receives an image direct from the lens, the light passing through the two mirrors. Colour screens are used in front of some or all of the sensitive plates, their colour being such that the negatives obtained upon the three plates represent the three primary colours or colour sensations, and that the coloured light passing through them, when the apparatus is used as a

viewing instrument, reproduces in each case one of the three primary colours. To secure this result, additional colour screens may be used in negative-making or viewing to ensure the correct photography of the colours, to equalise the exposure of the three plates, or to absorb such colours as may require eliminating for viewing purposes.

"I preferably fix screens suitable for negative-making in the apparatus, and control their colour for viewing purposes by a screen at or near the eyepiece, this being of such a colour as will absorb wholly or in part such colours as may be incorrect or of too great brilliancy.

"The casing or body is hinged preferably at the front lower edge, that is, the lower edge of the end to which the lens or eyepiece is attached, to a base, so as to be movable upon a horizontal axis, a slotted strut or arm, *A*, pivoted to the base serving in connexion with a set screw on the body to adjust the latter to any required angle. When the apparatus is used as a viewing instrument with three transparencies, the bellows front, carrying the lens rack and pinion, is removed, and a silvered mirror at an angle of  $45^\circ$  reflecting the image upwards at an angle of  $90^\circ$  is substituted, a magnifying eyepiece being affixed, *X*. To the upper side of the casing is attached a reflector, *B*, and to the lower side of the casing, or to the upper part of the base, another reflector, *C*, each movable upon a horizontal axis. The body of the apparatus is then pointed upwards, towards a bright sky or other suitable source of light. The mirrors at the upper and lower sides of casing are adjustable by means of a slotted strut and set screw in each case, *d* and *e*, so as to

properly illuminate the upper and lower transparencies. These mirrors are removable when the apparatus is used as a camera. The base of the apparatus is made in two parts, the upper part, *f*, being hinged or attached to the lower, *g*, so as to be movable upon a horizontal axis at the back end of the base, that is, the end furthest from the observer when viewing. A slotted strut and set screw, *h*, enable this to be adjusted at any required angle, either for raising the apparatus or for adjusting its position in regard to the source of light.

"The apparatus may be either single or stereoscopic. In the latter case, two lenses are preferably employed for negative-making, and stereoscopic lenses for viewing, the apparatus being made of such width as will allow of the use of plates to give the required pairs of negatives and of transparencies consisting of stereoscopic pairs of images."

### SOUTHIN'S VIGNETTING APPARATUS.

This consists of two thin plates or frames, *A* and *B*, of suitable material, about the size of an ordinary printing frame, with rectangular openings a little smaller than the size of the negative. The bottom plate, *A*, rests on the top of the printing frame, and has a clasp, *c*, at one end of it, and a bent arm, *b*, with a milled-headed fixing screw, *x*, at the other end. A slot, *r*, and screw, *c*, may be used instead of the clasp, *c*. This bottom plate is moved horizontally across the printing frame, and can

be instantly secured to it by the fixing screw, *x*. Screwed studs, *n*, are riveted to this bottom plate, and the top plate, *B*, falls on these studs, the top plate being slotted to allow it to move freely in one direction on the studs, this direction being in a transverse direction to the movement of the bottom plate. A spring, *x*, or springs, flat or spiral, are fitted between the top and bottom plates or frames. Milled-headed nuts, *L*, are fitted on the screwed studs above the top frame; these springs and nuts are for the purpose of raising or lowering the top frame to any

suitable height. A locking nut, *x*, is fitted to one of the screwed studs between the frames, *A*, *B*, this locking nut and the milled-headed nut above it instantly securing both the upright and lateral movement of the top frame. The top frame holds the vignetting card. This frame can be made of any suitable material. When made of a flexible material, portions of the plate are bent or moulded to form grooves, *n*, for the insertion of the card.

When made of wood, the cards run in grooves, *n*, in the frame, and are held securely by the bevels, *o*, on the inside of the frame, which bend up the end portions of the cards.

The cover lid, *p*, is employed to cut off all light but that which passes through the opening in the vignetting card. A light diffuser or filter is attached to the top frame, consisting of a sheet or sheets of transparent or coloured flexible material larger than the vignetting card, with a number of eyelet holes, loops, studs, or catches in it for the purpose of readily attaching it to or detaching it from the top frame, which is fitted with studs, holes, or catches for this purpose. It can also be attached to any ordinary printing frame in a similar manner and for a similar purpose.

### A NEW CAMERA.

MONS. J. G. SIEGRIST has designed a camera which, by means of a non-actinic envelope, can be adapted to "allow the actinic rays from the lens to pass by means of a movable slit orifice, which can be operated, by any convenient means, extremely close to the sensitive surface, and parallel to the same, without in any way injuring it."

This parallel movement can be effected in a variety of ways. Mons. Siegrist proceeds: "The method I have indicated in the accompanying drawing for moving the slit device is based on the transmission of the motion of a grooved pulley, *n*, by means of a cord or thread attached thereto, and passing round a small guide pulley so situated as to lead the cord to the slit device, which latter is guided in its movement of alternative disposition by any convenient means, so as to maintain its parallelism with the sensitive surface.

"I obtain thus a great speed of exposure.

"The plate or sensitive surface, *A*, being in practice always at the same distance from the back part of the lens, *n*, of the camera, it follows there is the necessity of having the special non-actinic envelope herein-after described in order not to interfere with the parallel movement of

the slit device to the plate, and to shield the plate from light other than passes through the slit.

"The essential features of the slit device are as follows:—

"My non-actinic envelope is formed of a quadrilateral or any other geometrical form, and is fixed, at *c*, to the interior of the side or end carrying the objective, *B*, the axis of which coincides with the centre of the quadrilateral figure. The other extremity of my envelope is fixed to the slit device at *d*.

"I have thus an envelope fixed by one of its ends, and adapted at its other end to be moved to a fixed distance in a plane parallel to the plates. This effect is produced with my non-rigid envelope, by reason of it being made with deformable, extensible, and contractible walls, these deformations, extensions, or contractions being brought about by the slit device in its displacement. In a word, my envelope, to respond to the definition hereinabove described, will be a photographic bellows, of which the forms and dimensions will be determined by the forms and dimensions of the boxes, of the lens, and of the slit device, on which it is fixed by its two extremities.

"In the middle position represented by the drawing, the side parts, *x*, *x'*, of my non-actinic envelope will be of equal length.

"The slit device in descending will contract or fold on itself at the part, *m*, and simultaneously develop or elongate the part, *x*. The inverse effect is produced when the slit device reascends. Nevertheless, one can insert in the middle of this envelope a rigid partition more or less extended, the importance being that the qualities of non-rigidity, of extensibility, and of contractibility—in a word, of deformation—is obtained at the two extremities fixed against the lens and the slit device.

"The pulley wheel, n, is operated by means of a spring barrel, s, or other equivalent means. The slit device is pulled down to the bottom of the camera by any suitable means, such as a cord attached thereto, and is retained in the set position by a detent or stop. When the exposure is to be made, the detent is released, and the spring barrel draws the slit device up across the plate or other sensitive surface by means of the cord.

### "VICOL."

The specification of this "colour" printing process, which is the invention of Messrs. T. T. Baker and M. S. Berger, is as follows:—

Add litmus, in preference powdered litmus, to water in proportion of about 1 ounce of litmus to about 6 ounces of water, then boil the mixture until the litmus is dissolved. When cold, filter the solution of litmus and mix it with the sensitive emulsion or solution in the proportion of about 40 parts of the litmus solution to 60 parts of the sensitive emulsion or solution the depths of the tints subsequently obtained varying with the proportion, of the litmus solution to the sensitive emulsion or solution. Apply by means of a roller or other convenient method the mixture of litmus solution and sensitive emulsion or solution to the surface of the material to be coated with it, thereby making a photographic printing surface on which photographs can be printed and finished off in the usual manner. Apply to the whole or any part of the surface of the printed photograph, with a camel's-hair brush or other suitable means, an acid or acid substance, by preference a five per cent. solution of citric acid, when a red or pink tint will be produced; or apply in like manner an alkali or alkaline substance, by preference a five per cent. solution of caustic soda, when a blue tint will be produced.

### A DISTINGUISHED LADY PHOTOGRAPHER.

In an illustrated interview with Madame Garet-Charles in the *Young Woman* for August, we are told that three years ago this successful photographer had practically no knowledge of photography, yet to-day she stands in the very front rank. She states that she has never advertised her work, her studio is in her own home (a house in the north-western quarter of London), and she received no training. "I began very comfortably," she says, "never taking photographs except by appointment, and never letting my work fall below a rather high standard; but it has meant a great deal of real hard work, and I have more than once been busy with my plates till past midnight; so that, physically, perhaps it is not quite the best profession for a woman. But the woman who is prepared to work hard, and is qualified in every other respect, may do very much worse than become a photographer. There is a good deal more in the art of photography than most people imagine. It is not merely the taking off and putting on of a cap. Even the character of the photographer has something to do with the work. To take a really successful photograph, you must have a personality. You must be pleasant, look cheerful, and make your sitter perfectly at home. Let there be as little form as possible, and absolutely no stiffness. I know photographers who prop the sitters up against a lot of furniture. That, to my mind, is exactly how not to take a photograph. Let your sitter be perfectly natural, have a quick eye for a good expression, and at that moment seize your opportunity. You must be very quick, you must have great tact, and, above all, you must never appear to be in a hurry. Let the sitter think that time is of no consequence."

Madame Garet-Charles never, or hardly ever, takes men. "The only man I ever wanted to take was Lord Kitchener," she says, "and I could not get an opportunity. But, generally speaking, I am not interested in men—as a photographer, I mean; so I leave the men to the men, and I think the men should leave the women to the women. A woman is a much better woman's photographer than a man. She has naturally a much better idea of what is natural and becoming in a woman. It is rather hard on the men, I admit, seeing that women are the best—practically, in many instances, the only—patrons. A man rarely has his photograph taken unless his wife or his lady friends make him, but a smart woman gets photographed every few months; she goes to her photographer as regularly as she goes to her dentist.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, August 23, at eight o'clock. Discussion, "Does Photography Benefit by Awards of Judges who are not Photographers?"

The *London Gazette* announces that, by Order in Council, the provisions of the International Copyright Convention will extend to Japan from the 15th ult., and to Montenegro from April 1 next.

THE latest Convention photograph to reach us is a 12×10 enlargement from a three-and-a-half-inch negative, on the Wellington film, by Mr. A. H. Ward, of Messrs. Wellington & Ward, Elstree. It is a group of the Convention Council, and our thanks are due to Mr. Ward for enabling us to add the picture to our collection of Convention mementoes.

THE Research Fellowships founded by the Salters' Company and the Leather-sellers' Company for the encouragement of higher research in chemistry in its relation to manufactures, tenable at the City and Guilds Central Technical College, being now vacant, the Executive Committee of the City and Guilds of London Institute will, before the commencement of next session, consider applications and elect candidates. The grant made by each of the Companies to the Institute for this purpose is 150*l.* a year. Copies of the scheme under which the Fellowships will be awarded may be had on application to the Hon. Secretary of the Institute, Gresham College, London.

CALCIUM CARBIDE FACTORIES IN NORWAY.—With its many waterfalls and a plentiful supply of chalkstone in some localities, Norway would appear to be more favourably situated, with regard to the production of calcium carbide, than countries where steam (and not water) has to be used to produce the necessary electric power. H.M. Consul-General at Christiania reports in a despatch, dated June 8 last, to the Foreign Office, that two calcium carbide factories have started work in Norway. The larger, of 3000 horse power, is situated near Hafslund; the smaller, of 1500 horse power, near Borregaard, facing each other on either side of the Sarpsfoss waterfall, above Fredrikstad. It is stated that the Hafslund factory is shortly to be increased to 5000 horse power. It has been built by the Electricitets Aktieselskab (formerly Schuckert & Co.), Nürnberg. Other factories are now in contemplation.

"ONE-AND-ALL" INTERNATIONAL EXHIBITION OF HORTICULTURAL PHOTOGRAPHS.—We have received the schedule of prizes to be given at this Exhibition, which will be held at the Crystal Palace in August 1900. The great success which attended the Exhibition of Horticultural Photographs held at the Crystal Palace during the week ending August 19, 1899, has determined the Association to greatly extend the 1900 Exhibition, and make it of a thoroughly international character. A minimum issue of 20,000 schedules of prizes will be printed. Ten thousand of these will comprise the English edition, and will be sent to leading photographers and horticulturists, not only in the United Kingdom, but in the United States of America, Canada, Australia, Africa, and to all other important countries where the English language is spoken. The remaining 10,000 copies will be divided into editions printed in French, German, Spanish, and Italian, and will be sent to the same class of people in those countries and their dependencies.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

26.....	Hackney.....	{ Excursion: Landon Hills. Leader, A. D. Fort.
26.....	West London.....	Excursion: Richmond Park.

### PHOTOGRAPHIC CLUB.

AUGUST 9.—Mr. J. Nesbit in the chair.

Discussion took place upon the previous week's proceedings, Mr. Foxlee showing a further test he had made with a solution of kochin that had been previously used and kept, one half of a plate having been developed with fresh solution, taking two and a half minutes, the other, with old solution, taking eight minutes, the result being that the latter was denser and somewhat harder. It was agreed that the old kochin solution gave a similar result to that of an old metal solution.

The Hon. Secretary showed three X-ray negatives of a child's hand with the bone of the first finger broken.

Mr. W. D. Welford showed a blokam, and explained the various manipulations in working same. It was acknowledged to be an extremely well-made and ingenious apparatus and well worth the price asked for it by the makers.

### FORTHCOMING EXHIBITIONS.

1899.

August ..... One-and-All Flower Show at the Crystal Palace (Photographic Classes). Hon. Secretary, E. O. Greening, 3, Agar-street, Charing Cross, W.C.

Sept. 22–Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.

- Sept. 25-Nov. 11..... Royal Photographic Society. Hon. Secretary,  
Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18-24 ..... Croydon Camera Club.
- „ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Repre-  
sentative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New  
York). Hon. Secretary for European Exhi-  
bition, H. Snowden Ward, 6, Farringdon-  
avenue, E.C.
- December 7-9 ..... Hove Camera Club. C. Berrington Stoner,  
24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

The following applications for Patents were made between July 31 and August 5, 1899:—

- STEREOSCOPIC APPARATUS.—No. 15,605. "Improvements in Stereoscopic Apparatus." W. THOMSON and THE JACHTO PATENT AUTOMATIC ADVERTISING LAMP COMPANY, LIMITED.
- DISHES.—No. 15,713. "Improved Photographic Dish or Tray for De-veloping, Toning, Fixing, Washing, and the like." P. V. LEVI.
- COLOUR PHOTOGRAPHY.—No. 15,753. "Improvements in or relating to the Production and Exhibition of Photographic Representations in Natural Colours." Communicated by L. Dacos Du Haeron. A. J. BOULT.
- CAMERAS.—No. 15,825. "Improvements in Photographic Cameras." Com-municated by the Vive Camera Company, United States. E. E. SHEDD.
- COLOURING.—No. 15,861. "An Improved Form of Coloured Photography to be used for Ornamental or Decorative Purposes." G. J. SERSHALL and A. F. BIDDLE.
- VIEW-FINDER.—No. 15,676. "Improvements in Photographic Finders or View-meters." J. E. THORNTON and C. F. S. ROTHWELL.
- VIGNETTES.—No. 15,863. "Improvements in Vignettes for Photographic Purposes." G. J. SERSHALL and A. F. BIDDLE.
- ACTINOMETER.—No. 15,864. "An Improved Actinometer for Photographic Use." G. J. SERSHALL and A. F. BIDDLE.
- BACKGROUNDS.—No. 15,950. "Artificial Backgrounds for Photographs." T. R. WATSON.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### OZOTYPE.

To the EDITORS.

GENTLEMEN,—The June number of the *American Amateur Photographic Magazine* contains an article on the subject of a new process of photo-graphic printing called Ozotype, a modification of carbon printing, the distinguishing feature being that a visible image is obtained by printing out upon paper which is sensitised by being brushed over with a solution containing "manganous" sulphate and bichromate of potassium (the formula of which is given), and that subsequently this print, after being washed and dried, is moistened in an acid bath, with a small addition of hydroquinone (formula given). At the same time a piece of carbon pigmented tissue is soaked in the same acid solution, and is then squeezed on to the moistened print. After setting up to dry, the print with the squeezed tissue is first subjected to a cold bath for thirty minutes, and then transferred to hot water, and it is said that the part of the pigment (as in the regular carbon process) which is not affected by light is dissolved away and the picture is obtained. I tried the process as stated, using sulphate of manganese and the bichromate solution, and proceeded to print out, obtaining a fairly good brown-coloured image. I then followed the directions given, and, after placing the print with its adhering tissue in the hot water, I could get no further, as the pigment

continued to adhere to the print, refusing to dissolve. I tried three separate times, with the same result.

My object in troubling you is to ask you if you can help me to the right solution, and, if you cannot do so yourself, could you, through the officers of the Royal Photographic Society, or through the inventors of the process in question, obtain for me the *correct formula* to enable me to make a further experiment? I only work as an amateur, but I am greatly interested in all that pertains to the subject of photography, and I was particularly struck with this new process, and should very much like to be able to attain the desired results, and, in the event of success, to demonstrate the process before our Camera Club members in this city, where I feel sure the process would be highly appreciated. I am told that the process is patented in England, and is successfully used there, and that a patent has also been taken out in this country; and in any communication on the subject I should be glad to know in what way the patent right would apply, that is, if any royalty would have to be paid, or any licence required to use the process.

Apologising for troubling you at such a length, I am yours, &c.,

COLIN NAPIER.

609, Marshall-avenue, St. Paul, Minnesota, U.S.A., July 28, 1899.

P.S.—I am from Liverpool, have been eighteen years in this country. One of my most intimate friends was the late Mr. Benjamin Sayce, whose name is recorded in your Almanac, and who was the first (or one of the first, at all events) to introduce the dry-plate process.—C. N.

[We fail to see, supposing the directions were carefully carried out, why our correspondent has not succeeded. It is possible that the carbon tissue is at fault. Does it work well when sensitised with bichromate of potash and used in the ordinary method of carbon printing? If it does not, that may account for the difficulty. If this should meet the eye of Mr. Manly, perhaps he will kindly set our correspondent right, and, at the same time, say under what condition the process can be worked by amateurs in America.—EDS.]

## VALUE OF ENGRAVINGS.

To the EDITORS.

GENTLEMEN,—I think I saw in the JOURNAL a short time ago an editorial note on the subject of old engravings and the high prices they have been realising at sales. I have a pair of very fine coloured en-gravings, by W. Ward, from paintings by G. Morland, called *The Farm-yard* and *The Farmer's Stable*, and published by "J. B. Smith, King-street, Strand, July 1, 1795." They have been in the family nearly a century, and, I believe, are very scarce. No doubt there are others in existence, but I have never seen their fellows anywhere. It would be interesting to learn whether they are commonly known or not, and perhaps the publication of this letter in your widely circulated JOURNAL may bring to light some information on the subject. The family have always been under the impression that the pictures were rare, and, to a certain extent, valuable as reproductions of G. Morland's paintings, but it is possible they have valued them too highly.—I am, yours, &c.,

Newport, August 7, 1899.

COLONEL.

[Some correspondent may be able to give an idea of the value of the engravings in question.—EDS.]

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPH REGISTERED:—

J. Stuart, Claverton, Helensburgh.—Photograph of late Dr. Bruce.

AJAX, and many other correspondents.—In our next.

E. C. HEWITT.—We are much obliged to you for your letter.

F. E. BARNETT (Brooklyn, N.Y.).—We do not undertake commissions of the nature specified.

G. L. GORMAN.—We would suggest that you communicate with Mr. Avery, of the Strand, who is demonstrating the film.

**W. H. HUNT (Willesden-green).**—We will communicate with you on the subject in the course of a week. In the mean while we shall be glad to see the letters and photographs.

**DAQUERRETYPE PLATES WANTED.**—O. P. Q. We do not know where you can get Daquerreotype plates now, as they are not stocked by any of the dealers of the present day. Possibly, if you advertised for them, you might obtain some.

**C. H. CROSBY (Chicago).**—We are much obliged to you for your letter and the enclosures. A short article on the subject shall appear in the course of a week or two. We were very much amused with the "chemical" story; the author's theories are all his own.

**PRECIPITATED GOLD.**—P. CONNELL. The reason why the solution turned brown directly it was mixed, and deposited a sediment, is either that impure water was used or that the solution was made in a dirty vessel. From the appearance of the deposit we should suspect the presence of a trace of hypo.

**TEST FOR PLATINOTYPES.**—C. WILTON. You may be right, that the so-called platinotypes are bromide prints. The simple test you ask for is a solution of bichloride of mercury. If a bromide print be put in that, the image will be bleached out, whereas a platinotype will be unaffected.

**PHOTO-MICROGRAPHY.**—NOVICIATE. The quarter-inch objective you have will do quite well for the work and will probably require no correction for chemical focus. We should, however, recommend you to use a much lower power to begin with, say, an inch and a half or two inches. After some experience is gained with a low power, then essay with the higher ones.

**STAINED NEGATIVES.**—T. BLEWITT says: "I have some hand-camera negatives that have become covered with small spots through contact with the silver paper while printing. The spots, about the size of a pin's head, show white in the prints. Can you tell me any method of removing them?"—Try King's solution for the purpose. It is sold by Marion & Co.

**GREEN PRINTS.**—NEMO asks: "Can you kindly tell me how to obtain prints the colour of that enclosed? I have tried all the toning formulae for bromide prints that I can find, but cannot get the colour. I should like to get it on P.O.P. if possible."—The only way we know of producing the colour is by the process by which the print was made, namely, the carbon process. Tissue of the colour is a regular article of commerce.

**FAULTY MOUNTS.**—LANCS says: "I have a number of mounts that cause silver prints mounted upon them to fade in two or three years, and have discarded them for the purpose. Now, it has occurred to me that they could be utilised for carbon pictures. Do you think they can safely be used up in that way, as they are costly mounts?"—We should say so, as it is very unlikely that the mounts would have any ill effect on carbon prints.

**BANKRUPTCY.**—O. O. says: "My late employer has become bankrupt, owing me a month's wages. He says he cannot pay me, and I shall have to take so much in the pound with the other creditors when the affairs are settled. Would it be any use suing him in the County Court, as I am told that wages of servants must be paid in full?"—No; you must claim against the estate, but you will be paid in full. If you apply to the receiver in bankruptcy, it is possible, as your claim is for wages, it will be paid at once.

**DUST ON NEGATIVES.**—W. S. W. says: "They are pulling down a house next door to me, and I left some whole-plates on a rack at an open window to dry. Dust from the building has settled on them and dried on, and I cannot get it off. Can you help me, as I cannot take the negatives again? It is doubtful if the dust can be removed."—The only thing we can suggest is to soak the plates in cold water for a few hours, and then gently rub the surface with a pledget of cotton-wool. With care, in this way, the particles may probably be got off.

**PRICE OF ETHER.**—COLLODION writes: "I use a good deal of ether at times, and I have just seen a German price-list in which the best ether is quoted at a price much below what it is here. Can you give me an idea of what the carriage of a few gallons at a time would be to this country?"—We cannot; but it would, we suspect, be considerable, owing to railway and other carriage restrictions. Possibly you are not aware that there is a duty on ethers imported into this country. If we remember rightly, it is about 26s. a gallon on sulphuric ether.

**POST AS OPERATOR.**—A. L. says: "I hold a first-class certificate of proficiency in photography from South Kensington, and I wish to obtain an appointment as operator in a high-class London studio. Will you please inform me the best way to proceed?"—We should say the best way will be to article yourself to a first-class photographer, so as to learn something about portrait photography. Tuition in the class room, however proficient you may become there, does not avail much in practical work in the studio. There posing and lighting are the chief essentials, and still more so is tact in dealing with the sitters, things only acquired by actual practice in a studio.

**REVERSED ENLARGEMENT.**—Z. L. writes: "I sent a negative, with cash, to be enlarged. When I got the enlargement I found that the figure, as regards right and left, was reversed. I returned it, with the request for another the right way about. In reply, I got an apology for the mistake, but saying, as it was a portrait, it did not matter, but, if I liked, another would be made for half price, which I refused to pay. Now they have sent the picture back. What can I do?"—Send the enlargement back, telling the enlarger that, if another is not furnished at once, you will proceed in the County Court for the money paid. We should like the address of that enlarger.

**LACK OF BRILLIANCY IN NEGATIVES.**—G. AND B. write: "We have been for some time in trouble with our negatives; there is no brilliancy in them, and the image itself on the ground glass is not brilliant. The lens is —'s cabinet, which we have had in use for years, and it is only the last month or two we have become troubled, so it is not the fault of the lens."—We should rather say that it is the fault of the lens, or rather its mount. Reblack the inside of that, as well as the inside of the camera. If that is of the bellows form, line it with black velvet.

**LENS QUERY.**—H. BETTS writes: "I want a rapid rectilinear lens of about nine inches focus. I find, on reference to the price-lists of first-rate opticians, that the cost is more than I can afford; but I find there are similar lenses of foreign make about a third the price. Are they as good as the more costly ones if they are stopped down?"—Cheap lenses of foreign make are of a very variable quality. The great advantage of a high-class instrument is that it can be used with its full aperture, thus securing great rapidity. When a bad lens is used with a very small stop, it will generally give a fair result.

**SENSITISING ALBUMEN PAPER.**—PRINTER complains: "The albumen paper we had in last, —'s make, curls up directly it is floated on the bath, and often wets the back. Can you tell me how to avoid this, as I have not had much experience in sensitising paper?"—This is by no means an unusual experience when the paper is abnormally dry, as it frequently is at this season of the year. The trouble may be overcome by gently breathing on the back of the paper directly it is put upon the solution; in a few seconds it will lie flat. Another way is to keep the sheets in a damp place for an hour or two before sensitising them.

**LENS QUERY.**—W. BELL writes: "The new anastigmatic lenses are very costly, and so are the R.R.'s of our leading opticians; but there are cheap (French make) imitations of the latter that are really very good. Can you tell me if there are any cheap (say, French) imitations of the costly anastigmatic lenses, and where they are to be had?"—No. All the new forms of lenses of the anastigmatic type are the subject of patents, and, until they expire, there will be no imitations of them. When they do expire, however, you must not expect them at the price of R.R.'s, as they are much more difficult to make.

**OPERA-GLASS LENSES FOR PHOTOGRAPHY.**—G. KINGSFORD writes: "I have a large opera glass, and I think of getting a mount made, so that the object-glasses can be screwed into each end, with a stop between them, after the manner of a R.R. lens, so as to be used for a hand camera. The lenses are somewhere about seven-inch focus. Will you please say if the combination will be rectilinear, and cover a quarter-plate with the full opening, which will be about two inches?"—The lens will be rectilinear, but it will not cover the quarter-plate with the full opening, or, indeed, with a small stop, as the combination will only be about three and a half inches focus. Also the field will be very round.

**CRACKED PRINTS.**—B. & Co. complain as follows: "We are much troubled by our prints (albumen) cracking all over the surface. We use —'s doubly albumenised paper, and the trouble seems greater in hot weather than it is in cold. The prints look all right while in the washing water, and it is only when they are dry that the cracks become apparent. Can you suggest anything by way of a remedy?"—The cracks are caused by the prints being allowed to curl up while drying and then being flattened out. The remedy is to keep them flat while drying—drying them between blotting boards under pressure. If the prints are mounted while they are wet, the cracks will be avoided.

**EXPIRED COPYRIGHT.**—DOUBTFUL writes as follows: "Many years ago a photographer here took a photograph of an old and interesting building, which has since been pulled down, and made the picture copyright at the time. Before he died he sold his business and negatives, this one amongst them, and the purchaser continued to publish them. I have recently copied this and one or two others, and sold them, and now I am threatened with legal proceedings. What I want to know is, How long does a copyright last? The one who took the photograph, and made it copyright, has been dead this fourteen or fifteen years."—Copyright endures for the life of the author and for seven years after his death. Consequently there is no copyright in this photograph.

**TONING.**—TONING says: "Could you kindly explain the cause of the following concerning toning? The paper used is the Ilford and also Cadett (gelatino-chloride). The formula used is the Ilford toning formula, consisting of gold and ammonium sulphocyanide. There is a stock solution of each, and just before the actual toning the two are mixed and made up with the proper amount of water. The process of toning usually takes just under five minutes; I tone either one or two sheets at a time. Before the toning, the prints are in the washing water about three-quarters of an hour, an alum bath being used half way for ten minutes, the strength of which is made roughly, without weighing. I have tried with and without salt in the washing, before toning; when salt was used for five to ten minutes, the prints passed through it previous to the alum bath. What I want to know is the cause of the following:—1. For the last few days the toning seems to have gone wrong, instead of taking five minutes the prints take ten to fifteen minutes. 2. I get fearful double tones; 3. and irregular toning. If a print happens to be uncovered in toning for even a quarter of a minute or so, a line shows. 4. Once or twice there has appeared a sort of sky-blue patch, unlike the toning blue. Do I wash the prints too long, or should the toning be made up long before using, or is it the heat, or what is the matter?"—1. Probably the alum solution is too strong for so long an immersion. 2. Try a weaker solution of alum. 3 and 4. That is quite what might be expected. The prints must be kept in motion, and always covered with the solution. It is better to make up the bath ten minutes or so before it is used.

## EX CATHEDRA.

At a recent meeting of the Photographic Society of Philadelphia, Mr. W. E. Partridge described the following interesting process of making enlargements by painting over a projected image. "Those of us," he says, "who want to make pictures, and make them of a size to go on the wall, can do so, and not have to be artists. Make your picture; then prepare to enlarge it, putting it in your enlarging frame; then take a piece of black canvas to enlarge on (no preparation is needed beyond a piece of tailors' chalk). Make your outline, correcting the drawing if necessary; then commence with zinc white, mixed up with gum water about as thick as oil paint, putting on your high lights first, and working towards black. This does not require drawing—it only needs the light and shade of the print before you. You can turn on your enlarging light at any time. If it is not right, let it dry, and brush it off with a whisk broom and begin again. It is the quickest of all processes for producing pictures, and has the advantage of quick erasing. It has also all the advantage of the old wood engraving in putting

white upon black and not black upon white, as in all of our other graphic arts. When you have finished you can, if you like, make a negative of what you have got."

\* \* \*

THE *Daily Telegraph* of Wednesday last contained the following interesting announcement:—"The Duchess of York, who is staying at Longford Hall, visited the Royal Castle Glass Works, at Hatton, and subsequently the Photo Decorative Tile Company adjoining. At the first-named place Her Royal Highness displayed great interest in the process, and ordered a number of articles to be made, and herself assisted in the process. At the Tile Works she sat for her photograph, to be reproduced in photo models [? enamels]. Her Royal Highness was accompanied by Lady Katharine Coke, the Earl and Countess of Lathom, Hon. A. N. Hood, Mrs. Crutchley, and Mr. Reginald Coke, and the entire party were photographed for reproduction in a group on the glazed tiles. The process is a comparatively new one, having been patented only about two years. From the works the party drove to the Old Castle at Tutbury, which is the property of the Duchy of Lancaster. John of Gaunt's Gateway and the dungeon where Mary Queen of Scots was a temporary prisoner were inspected, and the visitors partook of tea in the castle before returning to Longford."

\* \* \*

WE are sorry to have to announce the death, on the 19th inst., of the Rev. Canon St. Vincent Beechey, rector of Hilgay, Downham. Canon Beechey, who was in his ninety-fourth year, was probably the oldest living photographer, and he is said to have been the oldest living clergyman. He had been rector of Hilgay twenty-seven years, and instituted the electric lighting of the church, schools, and rectory. He was best known as having, while vicar of Fleetwood, founded Rossall School, and as being the son of Sir William Beechey, the eminent portrait painter and an intimate friend of Lord Nelson. A third of a century ago Beechey's collodion and the Beechey collodion dry plates were well known to photographers. The deceased gentleman was an accomplished photographer, and often contributed to these pages articles on the subject of his favourite pursuit.

SPECIAL interest attaches to the illustrated catalogue of astronomical instruments, observatories, &c., manufactured by Sir Howard Grubb, of Rathmines, Dublin, a copy of which that gentleman has been kind enough to send for our acceptance. It is illustrated by some half-tone reproductions of astro-photographs and several views in the optical works. A large variety of telescopes are described, and some of the famous instruments Sir Howard has made and erected are pictured. There are some exquisite collotype photographs of the late solar eclipse, the great nebula in Orion, &c., and altogether the catalogue, which is beautifully produced, is one that appeals strongly to those interested in astro-photography.

\* \* \*

MR. CHARLES SWEET, the well-known and able photographer of Rotherhay, N.B., sends us an illustrated pamphlet intended for circulation amongst his clients. It gives a view in half-tone of his new studio and many excellent reproductions of his admirable child studies, marine subjects, &c. Mr. Sweet's list of patrons is a large and aristocratic one. This is not to be wondered at, for his work is exceedingly good, and his enterprise in taking advantage of the half-tone process for drawing renewed attention to that work will, no doubt, add to the list.

\* \* \*

THE editor of our lively contemporary, *Ally Sloper's Half-Holiday*, informs us that we have been elected a member of Sloper's Club, which entitles us henceforth to affix to our name the letters M.O.S.C. A certificate of membership and a medal have also been sent to us. We assure our contemporary that we highly value the compliment that has been paid us, and will endeavour to act in all things not unworthily of the august position of a M.O.S.C.

## TONING METHODS II.

CONTINUING our remarks upon the adaptability of the various salts of gold for toning modern papers, we will first remind our readers that we have shown that gold chloride unites chemically with gelatine, forming an insoluble compound, and thus causing a waste of gold and tending also to unevenness in toning. Also we pointed out that the sulphocyanide and thiosulphate of gold have not this reaction, and therefore are in general use at the present day, more especially the former.

It is a very curious fact that the thiosulphate, or, to speak of it in its more familiar name, the hyposulphite of gold, or sel-d'or, has almost entirely disappeared from the photographer's laboratory. Yet, in the very early days of photography, it was almost universally employed, first for toning Daguerreotypes, and afterwards for ordinary paper prints. If, however, we refer back to some of the oldest toning formulæ in which the sel-d'or was employed, we are enabled to gain a glimpse of the reason for this disuse. Taking one as an instance, we find the ingredients to be 1 grain of gold, 4 grains of hypo, 4 drops of hydrochloric acid, and 10 ounces of water. It is evident on the face of it that with such a bath the resulting tones would be due to sulphur principally. We have already pointed out that hypo is an exceedingly unstable compound. In the above formula we have both gold hyposulphite and soda hyposulphite, and the addition of the hydro-

chloric acid would at once complete the decomposition thus:—

and again—

Here we see that the result of this mixture is, in the first instance, the formation of sodium chloride and sulphurous acid and the liberation of free sulphur, and in the second case the same reaction, excepting that aurous chloride is formed. The free sulphur would inevitably combine with the printed image, and more or less with the unreduced silver salts in the rest of the paper, giving rise to sulphur toning and a general yellowness over the whole picture. In those days very little was known of the real nature of the changes taking place in toning operations, and there is little wonder that, when alkaline toning was introduced, sel-d'or was soon almost forgotten.

The introduction of the modern gelatine-coated paper, however, was responsible for the reintroduction of sulphur combinations in toning in the shape of sulphocyanide of ammonium and gold. Although gold hyposulphite has been spoken of, yet it has not recovered the position it once held in the estimation of photographers. Sulphocyanide answers admirably, giving with ease a great range of tones. The principal fault found with it is the tendency in certain cases to give what are termed double tones or uneven toning. The causes of this we have already treated upon. With sel-d'or, however, there is very little to complain of in this respect, toning being even and perfectly under control, and when properly used the whites are perfect, whilst almost any shade to deep black can be obtained in the shadows. We would, in conclusion, recapitulate a few of the points necessary to be attended to for success, premising that the same applies to both sel-d'or and sulphocyanide methods.

First, all organic salts of silver or free nitrate of silver should be removed from the prints before toning by washing in water, then salt and water, and afterwards again in water. If this is not thoroughly done, there is a danger of insoluble yellow compounds of sulphur and silver being formed, which are not thoroughly removed by the hypo. Secondly, in making up the sel-d'or or gold hyposulphite, the solution of gold chloride or hypo should never be allowed to have a trace of acidity present, either before or after mixing. The gold should be slightly alkaline before mixing. Thirdly, the sel-d'or should not contain a large excess of hypo in its composition. The true sel-d'or, made by mixing equivalent proportions of hypo and gold in concentrated solution and then precipitating by alcohol, may be used, but is troublesome to make and by no means necessary. The double salt of thiosulphite of soda and gold is equally as effective provided the excess of hypo is kept within certain limits. The whole operation is perfectly simple, and we would recommend those of our readers who find toning troubles cropping up in their work to give sel-d'or a trial. The following will be found to give good results, but, as will be readily seen, is capable of considerable variation.

In a clean glass measure put 2 ounces of chloride of gold solution, containing 2 grains of gold chloride. In this put a strip of litmus paper, which will at once turn red from the acid present in the gold chloride. Now add a solution of carbonate of soda drop by drop with constant stirring until the litmus paper turns blue and remains so. In another measure dissolve eight grains of hypo in two ounces of water. As soon as solution is complete mix the two solutions by

pouring the gold into the hypo with constant stirring. Now make up to 10 ounces with water, add 20 grains of sodium chloride, and the bath is complete. The sodium chloride is not a necessity, but will be found to assist in keeping pure whites. When toned, wash and fix as usual.

We have thus far confined our remarks principally to toning methods in every-day use, but the subject is by no means exhausted. We must leave it to those of our readers who are experimentally inclined to go further into the subject. It is more than probable that the series of salts known as aurates would be found of great value. Auric oxide,  $\text{Au}_2\text{O}_3$ , combines with the oxides of most alkalies and alkaline earths to form a series of soluble salts, of which the sodium aurate might be taken as a type,  $\text{NaAuO}_2 \cdot 2\text{H}_2\text{O}$ . Salts of this series do not precipitate gelatine, and, if care be taken not to have an excess of the hydrate present, are stable and permanent both in the crystallised state and in solution.

### PRACTICAL PROBLEMS.

Few photographers, amateur or professional, practise their craft for any lengthened period without encountering difficulties which, for the time, seem inexplicable. Those who can do so wisely consult some friend who can look in at their work-room and critically go into the matter with them. Others, cut off from such assistance, must perforce seek the aid of text-books or of editors of journals or of manufacturers of materials.

We wish to point out that the photographer who approaches these problems in a scientific spirit is the most likely to arrive at a correct solution and a speedy delivery out of all his troubles. We are aware that, at the sound of the adjective "scientific," many of our readers will conjure up chemical formulæ, logarithms or researches such as those of Hurter & Driffield, and will protest that in their slight acquaintance, if any, with these things they find no practical aid. But science is after all very much like common sense, and many people who have not received any scientific training have, nevertheless, the faculty of approaching a problem in a really scientific manner. There is something not understood or misunderstood; something which happens which ought not to happen, the reason for which does not appear. The scientific spirit leads the photographer to so adjust his method of work as to frame an intelligent question in regard to the difficulty, to which nature may make an intelligible answer. For example, where spots appear on prints during toning and fixing, one would naturally modify the conditions of the routine—say, the water or the hypo—so as to trace the difficulty to its source.

Much assistance is, of course, desirable from a theoretical knowledge of the causes likely to lead to certain ill effects, and we do not for one moment wish to be understood to depreciate such assistance; but, at the same time, many difficulties would cease to be such if photographers possessing no great technical knowledge would seek to approach them in a spirit of investigation, assuming an agnostic attitude until reason appears for the assignation of the trouble to some particular quarter.

It is often difficult, and in many cases impossible, for any one unacquainted with the photographer's methods of working a process to pronounce a definite opinion in regard, let us say, to stained or faded prints merely by the inspection of several specimens. Indeed, the difficulty is often intensified by the

meagreness of the details—such as paper, toning bath, &c.—furnished by the applicant.

Very frequently no one is in a better position to help the photographer out of a difficulty than is he himself; we are speaking principally of spots and stains on prints, things which will make their appearance in the best-regulated establishment. We would, first of all, suggest that every practitioner should keep a watchful eye on the literature of subject in the photographic press, remembering that what are to-day the difficulties of others may be his own to-morrow. Practised workers are constantly recording the way in which apparently inexplicable troubles were traced to causes which, for a time, eluded detection by their very propinquity. Black spots, for instance, from grit in the wash water or particles of metal abraded from the bearings of a squeegee; spots on negatives simply caused by the use of a pyro-soda developer several times, whereby it is liable to deposit insoluble matter (or the same thing may happen by mixing fresh developer in a measure from which the old has not been rinsed). Then we need not call attention to the researches which various chemists have conducted at the request of manufacturers of certain papers, systematic filing of cases of this kind will soon place the photographer in possession of the cause and cure of almost all the ills that prints and plates are heir to. His own observation and judgment must be called into use to help him form a correct diagnosis of the malady from which his own products are suffering; but this is a far easier task when a description of the symptoms of previously diagnosed cases is at hand for comparison.

**Photographing Crystals.**—A correspondent calls our attention to the fact that the information sought by a correspondent a week ago with regard to the photographing of crystals might, in one phase, be found in a paper by Mr. W. J. Pope, read at a recent meeting of the Chemical Society. The apparatus used were an incandescent gas lamp, a lantern condenser, a polarising microscope (with the tube placed horizontally), and a camera arranged so as to be concentric with the microscope. The microscope can be used with or without an eye-piece, but by using it Mr. Pope states that a flare-spot disappears that shows without an eye-piece. We may here state that the "flare-spot" is simply a reflection from the microscope tube, and can be obviated by lining the latter with velvet. "The crystal preparation is placed on the microscope stage, and, by simultaneously racking the camera-back and the objective backwards and forwards, an image of the required size is focussed on the screen; the slide is then adjusted on the stage till the part to be photographed occupies the field of view. After finally focussing by means of the fine adjustment of the microscope, the picture may be photographed. Using a one-inch objective of N.A. = 0.25, and a total magnifying power of sixty diameters, the necessary exposure with such an apparatus as that described is from three to five minutes. When low powers, such as a one-inch or half-inch objective, are used, all the sub-stage condensing systems are removed. . . . The objects are photographed between crossed Nicols . . . mainly because the outlines of doubly refracting preparations, though nearly invisible in ordinary light, become plainly visible and stand out with great boldness when examined or photographed between crossed Nicols."

**Photographs of Lightning Flashes.**—At the present time, when thunderstorms are not uncommon and many facilities present themselves for securing pictures of lightning flashes, a few words on the subject may be useful. Our attention was drawn to the subject by the fact of a lady asking us to develop half-a-dozen negatives she had been taking of lightning flashes. We

developed the plates, or, rather, we passed them through the developing solution, and there was not a trace of a flash on any one of the plates. A few inquiries elicited the fact that our fair friend had used a "snapshot camera," and each time she saw a flash pointed the camera at it and snapped the shutter. A vivid flash leaves such a lasting impression upon the retina that such an error was excusable, but, as many of our readers will know, it would be next to impossible to obtain flash pictures in that manner. The plan to adopt simply consists in fixing the camera on a tripod and, first focussing for distance, and direct the camera (supplied with a wide-angle lens) to the part of the heavens where flashes have already appeared. Draw the shutter, take off the cap, and wait till a flash appears, and then expose another plate in a similar manner, and so on. The chance has to be taken as to whether the flash will appear in the middle of the plate or near its edge. The use of a wide-angle lens minimises the chance of losing the flash altogether. It should be stopped down to *f*-32.

**Photography and the Dreyfus Case.**—We have on a former occasion referred to the way that that unfortunate man, Captain Dreyfus, and his anxious wife, are persecuted by the ubiquitous photographer and cinematographer. The special correspondent of the *Standard*, writing one day last week, says that the proprietor of a vacant piece of land at the corner of the Military Prison at Rennes had erected a stand, from which, for a small sum, journalists and photographers could obtain an excellent view or snap-shot of the prisoner as he passed to the Court. However, this enterprising individual was afterwards notified by the authorities that he must keep his land clear during the time that Dreyfus was passing to and from the Court. Every one will commend the authorities for taking this step. Probably in this famous case photography has been utilised quite as much as it was in the celebrated Tichborne case, though perhaps less creditably. We all remember that, when this unfortunate man was degraded by having his uniform mutilated, he was photographed, and the photograph publicly shown.

**Faupers' Photographs.**—At the last meeting of the managers of the Central London District Schools, according to the *City Press*, a letter was read from Mr. H. Lockwood, one of Her Majesty's Inspectors of Schools, asking for photographs of boys and girls at the school, in addition to some that had already been given to him. He wanted them, he said, to show in the Poor Law Schools section of the British department at the forthcoming Paris Exhibition. The request, the report says, was referred to the House Committee. The application will doubtless receive due consideration from this Committee before it is granted. The children are paupers now, but they may not be in after life, and many of them will not care to let it be known that they received their education as paupers, and to know that their portraits as such had been shown in an international Exhibition. When, some time ago, a somewhat similar application was made to the Hampstead Guardians, by a photographer, to take portraits of the inmates of the workhouse, it was indignantly refused, and very rightly too.

**The Wellman Polar Expedition.**—A Reuter's telegram from Tromsø, dated August 17, says that the steamship *Capella* arrived there that evening with Mr. Walter Wellman and the survivors of his expedition. Mr. Wellman, it seems, had several unpleasant experiences—severe storms, an earthquake by which many dogs were crushed and sledges destroyed, and the men narrowly escaped with their lives. Mr. Wellman also met with an accident and seriously injured his leg, and the party was therefore compelled to retreat, dragging him on a sledge, making forced marches of nearly 200 miles to the headquarters of the Expedition. The continuous temperature during ten successive days was of 40° to 50° below zero. It is stated that several new lands and many islands have been discovered in Franz Josef Land, and much important scientific work was done by Dr. Hofman, Lieutenant Baldwin, and

Mr. Hanlan. No traces of Andrée, his companions, or the balloon were, however, found in Franz Josef Land. Photography was a feature in this Expedition, and it would be interesting to learn if any plates or films were exposed when the temperature was between 40° and 50° below zero, and what was the result, when they were (or are) developed.

**Camera for Stellar Photography.**—Our contemporary, the *English Mechanic*, has an illustration and description of a simple method of using an ordinary camera in connexion with a reflecting telescope. The camera employed—by no means a costly one—is fitted with a separate baseboard with a long slot in the middle. An iron strip, suitably bent, has one end firmly clamped to the telescope mount by means of a clamp, and the other end bent so as to be parallel with the baseboard. This end of the strip, which is slotted; is screwed on to the baseboard. When the focus is altered, the camera shifts up and down, and is clamped into position by means of its tripod screw. The camera is half-plate, and is supplied with a wide-angle lens.

**Aceto-cellulose.**—In a German chemical journal, Dr. C. A. Weber speaks very highly of Messrs. Cross & Bevan's acetate of cellulose, and prophesies an important industrial future for it. The nitro-celluloses or gun-cottons, including the well-known pyroxylin—the basis of collodion and of celluloid—resemble this new product in many respects, one important difference in favour of the aceto-cellulose being the non-explosiveness and the ability to stand a high temperature without decomposition that characterise the latter. Further, it is not soluble in alcohol, acetone, or ether, but dissolves in chloroform, nitro-benzol, and certain other bodies. Its great insulating properties render it useful for replacing mica for electrical purposes, while in many other cases Dr. Weber suggests its use in lieu of celluloid. It remains to be seen whether it could not be effectually utilised for many purposes of photographic technique.

**Coins as Units of Weight.**—A scientific paper recently had a paragraph on this subject, to the effect that "it is stated that the five-cent nickel coin of the U.S. currency was designed with special reference to its use as a unit of weight or measurement by the decimal system. It is exactly five grammes in weight and two centimetres in diameter. This, of course, is not an accident, and if there be any change in America's system of coinage, other convenient measurements and weights will be adopted according to the same system."

BUT America is not the only country where a coin has been made with a definite and convenient weight and measure. The fact is not sufficiently appreciated that in our own bronze coinage we have an excellent unit of weight and measure in the halfpenny piece. This coin weighs, when new, exactly one-fifth of an ounce, and its diameter is exactly one inch; the penny is of less convenient weight—one-third of an ounce. Hence five halfpennies or three pennies can be utilised instead of the usual brass weights for any non-commercial weighing operation. There is a real convenience in this system, for while it is not an infrequent thing for a weight to be missing just when it is most wanted, five halfpennies are always obtainable. It may be thought that in so common a coin the weights may be variable, but the contrary is the case. No halfpenny piece is issued which is more than .2 per cent. wrong in weight, one-fifth of one per cent. being what is known as the legal "remedy" in weight, and as this does not amount to one grain in an ounce, we may safely assert that the average unstamped ounce weight that one would purchase at the ironmonger's would not probably be more exact than this.

**A National Physical Laboratory.**—The report of the Committee appointed by the Treasury to consider the desirability of establishing a National Physical Laboratory was issued last week. It is favourable to the establishment of such an institution, and

recommends that it should be an extension of the Kew Observatory in the Old Deer Park, Richmond. The first object, as set forth in the report, of such an institution is to be the standardising and verifying of instruments for testing materials, and for the determination of physical constants. It is proposed in the report that the laboratory shall be under the auspices of the Royal Society, and that it shall nominate a governing body, on which commercial interests shall be represented, and that the choice of members of such body is not to be confined to Fellows of the Society. This, we think, is a very desirable recommendation. It is also recommended that the permanent Secretary of the Board of Trade should be an *ex-officio* member of the governing body, and that such body should be consulted by the standards office and the electrical standardising department of the Board of Trade upon all difficult questions that may arise from time to time, or as to proposed modifications or developments. When this proposed institution gets in working order, we may perhaps get some standard system of testing the speed of dry plates, a thing now much wanted amongst practical photographers. [See p. 540.]

**Royal Academy Winter Exhibition.**—It is announced that the next Winter Exhibition of the Royal Academy is to consist exclusively of works by Vandyk. This should be a highly interesting show to photographers, particularly to portraitists and those who make a feature of figure studies. This great master's works are almost entirely confined to portraits and figure studies, and at this Exhibition the public will have the opportunity of seeing such a collection that it may never have again. Our public galleries are by no means overstocked with Vandyks, and more is the pity. As we have said before, the Queen, in her private collections, has some of the finest examples of this famous artist's work in this country, and probably a larger number of them than is to be found in any other. By the way, the Vandyk Tercentenary Exhibition at Antwerp, to which we have referred before, is now open, and tourists who are taking their holidays in Belgium should not miss the opportunity of paying it a visit.

**The Spy Scare Again.**—This time Austria! The *Standard's* correspondent, writing from Vienna, says the Styrian papers report that a French captain, who was caught taking photographs of objects of military importance in Carniola, has been arrested and taken to Vienna. Possibly the authorities may, or may not, have some ground for this arrest, as the French captain may have been suspected of having ulterior objects in view. Be that as it may, the arrest of a suspected spy in any country is always sure to lead, for a time, to extra vigilance on the part of the minor authorities, and English tourists abroad (and there are hundreds at this season) should bear this fact in mind, and be careful where they are seen with a camera. We say seen with a camera, for we read that recently an amateur who was merely standing with a camera, watching some soldiers at drill at Dantzig, was arrested. He had made no attempt to take a photograph, yet he was, so it is said, kept in confinement for several days while his plates were being developed, and as they showed nothing at all compromising he was then liberated. A few days in "durance vile" materially curtails a holiday, so English tourists, beware!

#### JOTTINGS.

**VARDON!** Vardon! Vardon!—the name of the Englishman who is champion at Scotland's own game—this is the sound above all others that has been heard in East Lothian during the last few weeks. For golfers, and they form a remarkably large percentage of the population north of the Tweed, there is hardly such a thing as a Dreyfus case, and the drama at Rennes is dismissed from discussion before the second cup of tea is reached at breakfast. But Vardon and his doings at Nairn, Barnton, North Berwick, and elsewhere, are not off the tongues of the enthusiastic Scotch admirers

of the mighty Englishman for more than a few minutes. At New Luffness the champion drew a crowd of 4,000 people to see him play the local professional, and the camera in the hands of that very able worker, Mr. W. J. Croall, has perpetuated some of the notable doings on the Links, for the benefit of the millions at a distance who are interested in the champion's progress.

But the omnipresence of golf in Scotland is equalled, if not excelled, by that of photography, which has followed me with the tenacity of my own shadow during the last fortnight. One afternoon I am taken through the romantic glen of Dunglass, a beautifully wooded gorge near Cockburn's Path, and thence to an adjacent farm, which I discover to be in the occupation of Mr. Wyllie, an ardent stereoscopic worker, who makes excellent transparencies. In my wanderings I hear a great deal about stereography. There is an inclination amongst many photographers to take up this branch of work. A stereoscopic kodak would do much to hasten the "revival" of the stereoscope.

But the greatest enthusiasm for photography that I met in Scotland was shown by Miss Crooke, the accomplished daughter of the President of the Convention, whose guest I had the pleasure of being. One afternoon a picnic at Pease Bridge was held, and Miss Crooke whose photographic abilities are so great that if her inclinations tend that way her success in portraiture is assured, took two or three groups of the party. A late arrival home necessitated the postponement of development for some hours, and it was near midnight before the negatives were shown to me; but at half-past seven the next morning, toned, fixed, and washed prints from those negatives were placed in my hands by Miss Crooke herself, who had produced two capital pictures of the happy party of pretty ladies and brave cavaliers. Whether Miss Crooke will take up photography professionally or not I do not know, but in any case her inherited skill and her own marked ability should secure for her a high place amongst the select band of lady photographers.

To return to golf, into some of the mysteries of which it was my privilege to be initiated on the links at Dunbar and those at Barnton (Edinburgh). There is perhaps no pastime but golf the acquisition of the rudiments of which is so greatly facilitated by studying photographs of the game as it is played. Attitudes and positions are everything at golf, and their very immobility makes them susceptible of being most graphically portrayed by means of photography. The niceties of position in driving, approaching, putting, &c., can be perfectly shown by means of photography, and thus mature beginners who, like myself, are put through their paces for a day or two on the links may, at their leisure, by the assistance of photographs, practise those positions and attitudes, and thus get themselves into something like apparent familiarity with the game before venturing to risk the critical scrutinies of old frequenters of the links.

I have a note to herein thank Mr. Spence, photographer, of Dunbar, for a readily granted permission to use his dark room for changing purposes. But Mr. Spence deserves even wider recognition than this, for he allows any amateur to change his plates there without making a charge. At what point the return for this kindness makes its appearance I do not know, but I hope Mr. Spence's experience is that his readiness to loan his dark room brings him in some reward in the shape of increased business. He deserves it.

Berwickshire I was told is the garden of Scotland, and certainly the great farms in the northern part of the county seemed to be in a flourishing condition. If the success or failure of agriculture be the correct key to the state of a nation's business, it may be supposed that photography is partaking of the success which appears to be waiting on all kinds of industry in the district of which Edinburgh is the centre. Wherever I went, recently taken photographs were plentifully displayed; the Edinburgh dealers looked

busy, and the hand camera, if not so frequently seen as the golf clubs, was visible in the grasp of many a tourist. I saw some of the work intended for the autumn photographic exhibition in London, and I should not be surprised if at least one R.P.S. medal did not go to Edinburgh, which holds many staunch supporters of the Society.

An afternoon is devoted to Leith Docks, under the guidance of Mr. Thomas Aitken, the manager of the London and Edinburgh Shipping Company. The fine vessels of the Company have been well illustrated photographically by Mr. Aitken himself, who knows how to use the camera to the best advantage. One of our party was a gentleman who had only recently taken to photography. He complained that he frequently cycled twenty miles along a country road without seeing anything worth photographing. Relinquishing the camera that had been kindly lent me for some contemplated dock work, I offered to point out to our "new chum" a few of the opportunities which the life of the docks offered for making pictures by photography. The offer was accepted, and in something like two hours a couple of dozen exposures had been made on subjects full of pictorial promise. It had never occurred to our friend that dock life offered any scope for camera work, and his delight at discovering the wealth of material to be obtained was only equalled by the pleasure it gave me at acting the part of photographic instructor to a newly created enthusiast. Nothing is more agreeable than the office of photographic cicerone when you have students willing to learn.

After Edinburgh, which was seen at its best and clearest during the forty-eight hours of my stay there, the light being perfect both by day and night, the scene changes to Canty Bay, opposite the great Bass Rock. Here, in perfect seclusion by the rocks of many hues that were so often painted by the late Sam Bough, R.S.A., the hospitable friend of my host occupies the one habitable abode in the lonely bay. There are launch parties to the Rock in the course of the afternoon, and, as the machinery of the little cockle-shell goes slightly wrong in mid-channel, there is a spice of excitement in the proceedings. The ladies are naturally alarmed, but eventually the whole party reaches the mainland in safety. Then it becomes my turn to take a group in commemoration of the adventurous visit to the Bass. The servants are included, and among them is one whose face is a sea of delighted smiles while I am grouping and exposing. It transpires that this is the first time in her life that she has been photographed! If, prior to this, anybody had told me that there existed a member of the opposite sex who, living near a large town, had possessed the opportunity of being photographed, and had never availed herself of it, I should have found it hard to believe them. However, there was the smiling Scotch cook to prove that such strange things could be.

And this reminds me of the story told me about the Scottish minister who, being convinced that a patronage of photography was inconsistent with an observance of that commandment relating to the making of graven images, sternly refused all requests that he should sit for his portrait, on the ground that he would be breaking the Divine law referred to. But his friends were determined to obtain a photograph of him, and one day two or three engaged him in conversation while a fourth made a hand-camera exposure on him. The minister was highly indignant when the result was shown to him, but it is not recorded whether his unconsciousness of what was being done to him allayed his qualms of conscience. It is to be hoped so.

Craigcrook, the home of my host, Mr. Crooke, at Dunbar, not only possesses one of the noblest natural positions, looking out from the rocks to the sea, but internally it is a little Palace of Delight. At every turn the fine taste of the Convention President is seen, and the sincere love which he has for photography has led him to make considerable use of it for decorative purposes. Just as Mr. Crooke's studio in Prince's-street, Edinburgh, is admired for its refined unconventionality, looking at it simply as a photographer's studio, so even

in his country home you are bound to carry your admiration on to a warm recognition of the faultlessness of his surroundings.

It may be imagined, therefore, that my stay in the North, and particularly in this photographic palace, was a happy and busy one. To Mr. Croall and my Edinburgh friends my thanks are due for a pleasant taste of Edinburgh life. In making my acknowledgments to Mr., Mrs., and Miss Crooke, and the delightful lady whom I will call Fair Helen of Dunbar (another clever lady photographer), words can scarcely represent the extent of my grateful recognition. To one and all I send my best thanks. So away at midnight from the little Haddingtonshire town where I have passed so many pleasant hours; to awake seven hours later and wonder if it has all been a dream!

My holiday, which was to have been quite non-photographic, ended as it began, viz., photographically. From the grim rocks of Dunbar, and the soothing music of its troubled sea, I go to the placid land of the Broads, there once more to talk on the eternal subject of photography with that large-hearted master of it, Dr. P. H. Emerson. Half-an-hour is passed in glancing through the first copy of the new edition of his book, *Naturalistic Photography*, shortly to be published by Messrs. Dawbarn & Ward; the photographic outlook is discussed; and there, in sight of Oulton Broad, which is dotted with pleasure boats whose white sails almost glisten in the sunshine, my pleasant photographic tour is fittingly brought to a conclusion. COSMOS.

#### FOREIGN NEWS AND NOTES.

**The Preparation of Emulsions with aid of Electricity.**—On page 181 of THE BRITISH JOURNAL OF PHOTOGRAPHY this year we gave the particulars of H. Vollenbruch's application of electricity in the preparation of rapid emulsions. Professor Valenta has experimented upon the lines described by Herr Vollenbruch and communicates the result to the *Photographische Correspondenz*. A cylindrical vessel, thickly plated with silver, was fitted with a wooden cover, and through this was inserted a thickly silver-plated, branching copper wire. The vessel was light-tight and the wire was kept from contact with the sides of the vessel. The wire was connected with the positive and the wall of the cylinder with the negative pole of a Meidinger cell. According to Vollenbruch's directions a quantity of gelatine, soaked in silver nitrate, was broken up and placed in the vessel with the requisite quantity of bromide, to which two per cent. of ammonium chloride had been added. The wire was inserted, the vessel closed, and the electric current passed through the emulsion. Trial plates were coated from time to time, washed, dried, and exposed. According to the sensitometer, the plates were very slow, and, after twelve hours' exposure to the current, reduced silver was found in the apparatus. An unripe bromide emulsion similarly treated also gave negative results, and after the experiments were completed the surface of the wire and the interior of the vessel were found to be covered with a rough coating of silver. The experiments did not show any beneficial effect in ripening the emulsion, but possibly under different conditions Vollenbruch's process may be successful.

**A New Asphalt Process.**—The same periodical also draws attention to a new process, published by F. Alberini in the *Bulletino della Soc. Fot. Italiana*. Alberini has noticed that prolonged exposure to light renders asphalt to a certain extent soluble in alcohol or even water. If a plan or line drawing is placed upon a sheet of zinc or other support coated with a solution of Syrian asphalt in benzine (0.70), 70 grammes to 1000 c.c., and exposed for five or six hours to the sun, a positive may be developed. Two or three hours' exposure will suffice if the original is a transparency. For the exposure the printing frame should be placed so that the sun's rays fall upon it obliquely, otherwise the centre of the plate will not develop properly. Alberini thinks this peculiarity may be due to over-heating of the asphalt by exposure to perpendicular sunlight. After exposure, the plate should be developed by diffused light. Immerse it in alcohol (40°) for a few minutes, let it drain, and then remove the exposed asphalt mechanically, by pouring on alcohol and rubbing with a pledget of cotton-wool. When fully developed, wash the plate under the tap, and etch for about a minute with a two per cent. bath of dilute nitric acid. Repeat the etching two or three times and sponge the plate between each bath. The plate may then

be treated and printed as an ordinary line etching on zinc. Alberini prepares it by brushing it with a solution composed of—

Decoction of gall nuts .....	100 c. c.
Nitric acid .....	4 "
Hydrochloric acid .....	2 "

The decoction of gall nuts is prepared by boiling 125 grammes of powdered gall nuts in five litres of water until the quantity of fluid is reduced to two-thirds. After brushing over the plate with the acid gall-nut solution, wash it and rub in a twenty-five per cent. solution of gum. The plate should then be allowed to dry. Before printing, wash away the gum with water and remove the asphalt with turpentine or benzine. Roll up with a fatty ink.

**Hydroquinone and Iodine.**—The *Photographische Chronik* mentions that the introduction of adurol should again draw attention to the use of iodine in conjunction with hydroquinone for development. It is said to render the developer much more rapid, and give at the same time remarkable vigour to the negative. The following formula is recommended:—

Water .....	100 c. c.
Sulphite of soda .....	4 grammes.
Hydroquinone .....	1 gramme.
Saturated solution of soda .....	10 c. c.
Solution of potassium bromide .....	3 drops.

Add to the above 3 drops of the following solution:—

Water .....	15 c. c.
Iodide of potassium .....	5 grammes.
Iodine .....	1½ "

To the latter 250 c. c. water should be added so soon as the iodine is dissolved.

**The Reducing Power of Developers.**—In the *Photographische Mittheilungen*, Dr. Lüppe Cramer takes exception to the method by which Dr. Andresen has measured the relative reducing power of certain developers. This consists in preparing silver bromide by pouring an aqueous solution of potassium bromide into a solution of silver nitrate. After the silver bromide thus formed has been washed, a certain amount of the developer, mixed with alkali and sulphite, is poured into it, and the quantity of silver reduced is determined. The relative weights are taken as representing the relative reducing power of the developers in question? Dr. Cramer inquires of what value is this in relation to the latent image. He remarks that the flocculent or powdery form of silver bromide differs so much from the granular emulsified form that what may be true concerning the former is untrue concerning the latter. As it was also found that the same results followed whether the experiments were made by artificial light or in the dark room, they cannot be accepted as conclusive for a photographic plate which requires exposure as a preliminary to development. Dr. Cramer also holds it to be a mistake to regard the amount of silver reduced as the measure of the power of the developer. By such a rule a highly restrained hydroquinone developer should be taken as more powerful than a metol developer without restrainer, as the quantity of silver reduced by the former would certainly be in excess. Dr. Cramer considers that the most rapid developer is that which gives the best image with the shortest exposure, or, in other words, the best range of gradation for production of the print. The capacity to do this he would take as a definition of the expression "reducing power."

**Warm Tones on Lantern Slides.**—According to the *Bulletin* of the Association Belge, Lumière's pyro-acetone developer should be very suitable for this purpose. Sixty grammes of anhydrous sulphite of soda are dissolved in hot water and allowed to cool. Add 12 grammes of pyrogalllic acid and make up the total quantity with cold water to 600 c. c. This suffices for the development of twelve lantern plates. For use take 50 c. c. of pyro solution, 10 c. c. of acetone, and 50 c. c. of water. The image will be of a warm black colour. With more acetone up to 30 c. c. the colour may be modified through various shades to a fine warm brown; 40 c. c. of acetone will yield a sepia, and 50 c. c. a very bright, almost red sepia. The solution discolours quickly, but does not stain the film.

When using a large quantity of acetone (50 c. c.), crystals will sometimes form and adhere to the film. This should be avoided, as it affects the image.

**A Kinematograph Competition.**—The Società dei Bagni di Mare, Monaco, invites the users of the kinematograph to send in pictures for competition, and offers the following prizes: one of 10,000 liras, two of 5000 liras, two of 2000 liras, 6 of 1000 liras, also a certain number of honourable mentions. Each competitor to whom a prize is awarded will also receive a medal and certificate. The competition is exclusively confined to amateurs, but without restriction to nationality. The films must be 35 mm. broad, and perforated with the American standard gauge. Each competitor must send in not less than three pictures, and each of them must not have been previously exhibited. The negatives and one print from each in black or colours must be packed in a box inscribed with a motto. The motto with name of sender must be forwarded by post in a separate envelope. All pictures must be sent in between December 15 and January 15 next. The jury will consist of artists and amateurs, and special attention will be given to the originality, the artistic merit, and photographic quality of the pictures. The company reserves to itself the right to exhibit the pictures during the year 1900, either at Monaco or at the Paris Exhibition, and will return rejected pictures carriage-paid within two months of the decision of the jury. All pictures must be sent carriage-paid, and it is desirable that they should be packed in tin cases.

**A Kinematograph for the Blind.**—The *Photographische Chronik* mentions that Dussand has made an adaptation of this instrument, by means of which the blind, through the sense of touch, may be given an idea of objects in motion. It has thus been possible, through a rapid succession of raised impressions, to represent birds in flight.

#### THE SILVER IN THE PHOTOGRAPH.

We have been favoured by Dr. R. E. Liesegang, of Dusseldorf, with the following chapter from a new work which he is about to publish on the Physics of Photography; and, as it has some bearing upon the discussion which has recently taken place concerning the formation of the photographic image, we thank Dr. Liesegang for thus opportunely enabling us to place a translation of the same before our readers:—

Lying before us, side by side, are a finished negative from a gelatino-bromide plate and a gelatino-chloride print, which has been fixed but not toned.

The difference in the colour is remarkable. One is an intense black, and the other a reddish-yellow.

Yet chemical analysis shows that both are formed of metallic silver, and it follows that the difference in colour is not due to difference in their chemical composition.

If both are examined under the microscope, it will be seen that the dry-plate image consists of black particles of silver lying adjacent to each other; but, upon examining the chloride picture, or preferably a transparency made upon glass with the same emulsion, we are unable to discover any particles in the silver image.

The thought at once occurs that the difference in colour depends upon the difference in size of the silver particles.

This view is supported by a number of facts.

If we compare the chloride and the bromide plates before exposure, the former is very transparent and of a slight milky appearance, but the latter is merely translucent, and not unlike a sheet of paper. The subsequent modification of the metallic silver evidently depends upon the coarseness of the salt of silver from which it has been reduced. It is possible to prepare films of gelatino-bromide which are also fairly transparent by not allowing the emulsion to ripen. Films of this description exhibit a much finer grain when examined under the microscope, and yield red images when developed.

A similar interdependence of colour and size of grain may be traced when printing-out papers are developed. If a slightly printed gelatine print is developed with gallic acid, the depth of colour may be increased to any desired extent. If the exposure is short, the image will be greenish-black in colour after fixing, but with full exposure the tone ranges between red to brown. Closer study of the process shows

that the influence of the time of exposure upon the colour is only secondary. Briefly exposed prints require more development than those which have been fully exposed. The duration of development determines the subsequent tone. The intensification of the image is brought about by the action of the gallic acid in reducing the nitrate of silver in the film to the metallic state. This is precipitated in the nascent condition upon the exposed particles of silver chloride. The longer the image remains under development, the larger will the particles of metallic silver become.

I said that bromide plates could be made to yield red tones if the silver salt were in a very finely divided state. In practice only coarser-grained plates are used, because they require less exposure for production of the image. The physical process by which the coarseness of the grain of a dry plate is determined is one of great importance in their manufacture.

If an aqueous solution of nitrate of silver is poured into a solution of gelatine and potassium bromide, the same chemical process occurs as when plain solutions of the two chemicals are mixed. The solution becomes cloudy and milky. If allowed to stand, the silver bromide is not precipitated, but held in suspension, and consists of very fine particles supported by the gelatine in solution. This is called an emulsion. The silver bromide is not actually dissolved, for the gelatine is no more able to effect this than the water. If the emulsion is examined with a microscope, particles are discovered which, from their minuteness, fail to precipitate.

This is the principal difference between a true solution and an emulsion. In the former case the substance is divided to such an extent that, under the greatest possible magnification, no definite particles can be discovered. In the case of colourless salts, as, for instance, table salt dissolved in water, there is no apparent difference between it and plain water.

Emulsions possess properties which differ considerably from those of solutions, because of the difference in size of the merely floating particles as compared with those which are actually dissolved. The most important of these in photographic practice is ripening. If the emulsion is kept warm for some time, so that it remains in the fluid state, the grain will become coarser; the single particles form aggregations. Eder has shown that the grain of a bromide emulsion in the fluid state increased in diameter from 0.0008 to 0.0003 mm. After the lapse of fourteen days small clots of 0.02 to 0.04 mm. diameter were formed, and these were visible to the naked eye. The increase in coarseness of the grain is considerably accelerated by heat, and dry-plate manufacturers therefore boil the emulsion. A distinct indication of the progress made in ripening an emulsion is the change of colour by transmitted light. Immediately after mixing, the colour of a thin film will be yellowish-red, but later it will turn to reddish-violet, and finally to grey-violet and grey-blue.

If glass plates are coated with unripe and ripened emulsion, the former will require many times more exposure than the latter to produce a similar image after development with the same developer. *The emulsion when ripened yields more sensitive plates than in the unripened state.* This is the cause of the grain perceptible in negatives taken upon very sensitive plates. (This is especially noticeable in enlargements, and it is therefore desirable in practice to use slow plates for negatives which are to be considerably enlarged.)

There is apparently no chemical change in the process of ripening. The silver bromide is perfectly formed at starting, and the particles have only grouped themselves into larger aggregations. If the ripening is carried too far by keeping the emulsion warm for too long a time, the grains of bromide will become so large that the gelatine cannot hold them in suspension. They will then be partly precipitated. But before reaching this stage the emulsion will be useless for the preparation of dry plates, and fog will result upon development.

It has been supposed that the size of the particles of silver bromide emulsion before exposure determined the grain of the metallic silver forming the negative. But this need not be the case.

In the first place it is possible that the particles of silver bromide are not wholly reduced by the developer. Secondly, it is possible that the grain becomes coarser by precipitation of nascent silver. Thirdly, the particles of silver in the film may agglomerate and form larger aggregations. With regard to the first point, it is first necessary to refer to modern ideas concerning the process of development of the latent image. Whether we agree with Eder (sub-bromide theory), or with Abegg (nascent silver theory), it must be conceded that less silver is affected by light than is reduced by development. As some time is necessary for the reduction to spread to the unaffected bromide, it must be inferred that the aggregations of silver bromide are not always com-

pletely reduced. This would imply a reduction in the size of the grain. No microscopic investigation of this has yet been made, but the behaviour of chemically developed chloride plates (as used for lantern slides) appears to indicate the correctness of this supposition. With short exposure these yield greenish-black, and with long exposure red tones. An accurate examination of the case shows that the time of exposure is quite secondary in the production of tone. In reality it only depends upon the time of development, which, of course, must differ according to the exposure. The image was found to be redder in tone in proportion to the shortness of development, and the redness of colour always points to silver in a state of very fine division.

A growth in the grain of the image will only occur when there is physical, in addition to chemical, development, that is to say, when a free salt of silver is reduced by the developer and the nascent silver is precipitated upon the exposed particles of silver bromide. The free silver salt, which plays the important part in this process, may be produced by adding such chemicals to the developer which have the power of reducing silver haloids.

Two such instances occur in photographic literature. Neuhaus states in his *Researches concerning Lippmann's Colour Photography*: "It has hitherto been supposed that suitable plates for this process are and must be grainless. The bromide plates prepared according to Valenta's and Lumière's formulæ (mixing temperature of the emulsion 40° C.), which render colours in the best possible manner, have a distinctly perceptible grain. *The size of the grain before and after development is not the same.* Before development the measurement is 0.0001 to 0.0003 mm. As the half-wave lengths of light to which the eye is sensitive range between 0.00019 and 0.00038 mm., it is evident that the grain is of the same average diameter as the half-wave lengths. Under the influence of ammonia the grain coarsens remarkably in the process of development. The diameter after development amounts to 0.0005 to 0.0015 mm., and is consequently considerably more than the half wave-length."

The second instance is taken from Schumann, who had to pay especial attention to the size of the grain in making his noted spectrum photographs.

He exposed a plate normally, and cut it into three parts. The first was developed with a normal pyro developer, the second was developed with a small addition of bromide of potassium, and the third with a large addition of the same. The well-known effect of the bromide became perceptible, and the third strip showed very considerably more contrast than the first; but an unknown property of the bromide of potassium was observed, and its power to increase the contrast may be only secondary. The first strip was very fine in the grain, and its structure could only be seen with the microscope. The third strip, on the other hand, was very coarse, the particles of silver being separated by clear gelatine and almost as large as the grain of a process print. The second plate had an intermediate grain. Schumann expressed the idea that the potassium bromide had dissolved a small quantity of silver bromide, that the developer had reduced the silver, and that the latter in the nascent state had deposited upon the image, as in the process of physical development.

I think it necessary, however, to point out that, in both cases, emulsions of extremely fine grain are involved. The individual particles can be reduced completely with greater rapidity than can be the case where the grain is coarser. With the latter, however, the loss of silver from imperfect reduction may be greater than what may be gained from the nascent silver. We should not therefore expect similar intensification in the case of very sensitive plates.

But the possibility is not excluded that nascent silver produced in this way plays some part in certain processes of development. A very small quantity of hyposulphite of soda is sometimes added to the developer to obtain as much as possible from an under-exposed plate. Probably this dissolves a small amount of silver bromide, which is then reduced by the developer. It is not necessary that there should be a perceptible intensification of the image. Perhaps the fresh nascent silver only contributes to the chemical development.

Should not sulphite of soda, which is also a solvent of the silver haloids, act in a similar manner?

The third possibility by which the grain may increase in size will be apparent to those who have overstepped the mark in drying a negative by heat. If the film does not reach the melting point, there is generally a visible intensification of the image, the film becomes so coarse in the grain that the particles are distinctly visible. Exactly the same thing may happen when a much under-exposed plate is left for some time in a strongly alkaline pyro developer. In both cases the film is softened, and this permits the particles of silver to agglomerate.

## WHAT NOT TO DO IN PLAIN SILVER PRINTING.

*[Journal of the Photographic Society of Philadelphia.]*

In the older descriptions of the plain silver process the point most emphasised was to "keep the image on the surface," for, it was said, if the image be allowed to sink into the fibre of the paper, dulness and flatness will result. This idea was partly due to a misconception, and partly to a different standard of work in those days. It is true that if a sheet of ordinary photographic paper be salted by long floating or immersion in such a manner that the salt penetrates well into the fibre, and then be sensitised by the usual short floating, the prints will likely be flat and "sunk-in" looking. But is this due to the fact that the image is not confined to the surface? No; it is because there is so much salt present that there is not sufficient excess of free silver nitrate to properly sensitise the silver chloride: for it is a well-known fact that, while silver chloride alone readily darkens to a certain tone, it does not reach the full depth except in the presence of silver nitrate. If this paper be soaked in the silver bath until an excess of the latter salt obtains throughout the entire thickness, it will then be found to print properly, and without any sunk-in appearance, though here, certainly, there can be no question of the surface image. So far from a thin, superficial image, tending to brilliant blacks, the reverse is the case, since the thicker the sensitive film the thicker will also be the resulting deposit and the more thoroughly will it obscure the white colour of the underlying paper. A mealy black is simply one in which the deposit is so thin or imperfect that the paper can be seen through it.

But, as has been said, another factor made itself felt in the precept to keep the image on the surface; by so doing greater sharpness could be obtained in the detail. This is true, for it is evident that, as the action of the light penetrates into the paper, the distance between the negative and that stratum of the paper where the printing is going on is constantly increasing, and therefore the image must become less sharp, just as it would were we gradually to withdraw the negative. In the old days this was a consideration of importance, for, if the negative and print were not microscopically sharp all over, the work was a failure. But with the advent of the platinotype all this was changed, and we have come to recognise that the merits of a picture are not gauged by the amount of incisive detail which can be made out per square inch of surface.

Such appears to have been the origin of the mistake, and it has been diligently spread and perpetuated. One of the most prominent professional photographers in this city told me a few days ago that he would like to make plain silver prints, but, after trying a number of different papers, had been obliged to give up the idea, because he could find none which would keep the image sufficiently on the surface to give the proper brilliancy, and asked me what I thought of resizing the paper with glue. I do not say that it is impossible to get good, rich blacks from a superficial image, for, with carefully prepared paper, a suitable negative, and, not least important, a suitable light, it undoubtedly is sometimes possible to get fine results. We have all seen such. But the difficulty of making a really first-class print is so great, compared with the ease by which any number with purplish-gray tones or mealy shadows may be turned out, that one rarely sees silver prints exhibited. But once use a rough-surfaced, slightly bibulous paper, get the print well into the fibre, and the difficulties disappear. Any hard-textured, firmly compressed paper is to be rejected. Ordinary photographic paper is not very satisfactory. The best which I have ever found was the old cold-pressed Whatman drawing paper, made ten or fifteen years ago. So far as I know, however, this cannot be obtained. The present Whatman "N" is very soft, and gives beautiful results, but lacks the strength and coherence necessary to withstand the long immersion in the different solutions and wash water incident to silver printing. If one tries to use it without sizing, about half the prints are lost before they have been sufficiently washed, and sometimes soften to such an extent that in lifting from one dish to another the piece taken hold of tears off before the print has been raised from the liquid. This difficulty can be remedied by sizing, though only with some loss of the soft effect. However, if the sizing be kept at the lowest limit, the difference is not very noticeable, and we obtain a paper which is capable of readily yielding beautiful prints. The examples which are in your hands this evening were made on this paper, according to the following formulae:—

Whatman "N" paper is soaked for about eight minutes in—

Gelatine .....	2½ drachms.
Sodium chloride .....	2½ "
Water .....	30 ounces.
Chrome alum (ten-grain solution) .....	1 ounce.

Care must be taken to watch for air bubbles, so that they can be promptly removed, and the paper is best turned over once or twice in the bath. It is very desirable to use chemically pure sodium chloride, as, if the ordinary domestic article be employed, the salted paper will not keep, owing to the presence of magnesium chloride, which is found in table salt. On account of the hygroscopic qualities of the magnesium salt, the paper is always damp, and decomposition is likely to result.

After the paper is dry, and shortly before printing, sensitise by brushing freely with the following solution:—

Citric acid .....	120 grains.
Nitrate silver .....	70 "
Water (distilled) .....	1 ounce.

As soon as the paper has once more become dry it is ready to print, no fuming being necessary. The printing is carried rather farther than for albumen, and thin negatives are much better exposed under green glass. As it is difficult to get such glass free from blebs and other imperfections, the following plan, suggested to me by Mr. Ives, may be used instead: Fix an unexposed gelatine plate, wash and soak in a strong solution of naphthol green. This stains the gelatine film, and when dry it answers every purpose of green glass. After printing, wash thoroughly until all the free silver nitrate is removed, and tone in any suitable gold bath. The present prints were toned with the common bicarbonate bath, used a little weaker than usual, or about 1 grain gold chloride to 16 ounces of water. In a strong bath the prints tone so rapidly that it is difficult to stop at just the proper point. If a pure, neutral black be desired, the toning is carried a little farther than for albumen. The treatment after toning is the same as for albumen.

The only objection which can be made to the use of absorbent paper is that more silver is needed to sensitise and more gold to tone. Thus, a little less than two ounces of the sensitising solution are required for one dozen 6½ × 8½ prints, and about three grains of gold chloride. The cost of the above quantities will be about thirty cents, while the paper itself cost 13 cents more. If we allow 5 cents more for the salting bath, hypo, and incidentals, we get a total of 48 cents per dozen. This estimate is based on retail prices, and by judicious buying can be considerably reduced. As here given, it will be found about one-third less than bromide or aristotype, and less than half as much as platinum. So that, even in the expensive form advocated, silver printing is still the cheapest process by which first-class results can be obtained. In practice the advantage in cost is still greater, because with silver almost every piece of paper exposed results in a good print, which, except in the most skilful hands, cannot be said of most processes. As to the results to be obtained, I prefer to let them speak for themselves. No. 1 is from a flat, weak negative, that will scarcely give a platinum print. No. 2 is from a good negative, full of rich half-tone, but with almost clear glass under the bridge. No. 3 is a well-known view chiefly composed of black and white. It and the shadow in the preceding show what can be done with blacks, and the three taken together cover about the entire range of practically useful black tone values. No. 4 is a print from a rather hard negative on Whatman's "N" paper without any sizing, but the same quantity of salting. Of course, I do not claim any originality in regard to the idea of using drawing paper to make prints on, but if the direct stand which is here taken, in opposition to the idea of keeping the image on the surface, shall have some effect in doing away with this popular, but, as I believe, hurtful, delusion, I shall feel that this paper has served a useful purpose.

DR. CASPAR W. MILLER.

## TRICOLOUR TRANSPARENCIES FOR PROJECTION AND THE STEREOSCOPE.\*

## B.—The Staining of the Gelatine Images.

THE colouration which gelatine assumes in solutions of dyes is not, as is generally believed, produced by the absorption of the liquid, but must be ascribed to a chemical combination, if only a loose one, with the dye.†

For this reason also all dyes are not suitable for colouring gelatine images, and, as in dyeing material, certain dyes must be used in an acid, others in an alkaline solution. For instance, gelatine is not coloured at all by iodine green in an acid solution, whilst Höchst Neublau will stain only from acid and not from alkaline solutions. The gelatine thus sometimes plays the rôle of an acid, sometimes that of a base, and combines with the dye bases or acids and forms coloured compounds of the character of salts. As a rule, however, it will take acid dyes more readily, and therefore these are to be preferred for staining the gelatine images. The eosines, the rhodamines, and all the sulphonic acid dyes, are therefore excellent stains for gelatine. As the commercial dyes are potassium or sodium salts of these acids, the addition of a little acetic acid to their solutions, which causes a decomposition of the salts, renders the dyeing process considerably easier, whilst the presence of a strong alkali quite stops their staining power.

The combination of the dye with the gelatine is, as already mentioned, only very loose, and even continuous treatment with water is sufficient to produce a gradual discolouration.

It is possible, therefore, to wash the coloured gelatine images with acidulated water without altering their colour; by treatment with pure water the colour may be weakened, and with dilute ammonia the pictures may be entirely decolourised.

The following dyes, with the addition of acetic acid, are specially suitable for staining gelatine:—

Xylinin ponceau or Bleibrich scarlet stain a scarlet red corresponding to the spectral colour between B and C.

\* Continued from p. 471.

† Hübl, *Die Dreifarben Photographie*, p. 141.

Methyl orange stains a yellowish-orange, corresponding to the spectral colour at D.

Naphthol yellow SL, stains a pure yellow.

Acid green stains green, with a faint bluish tinge. This colour is complementary to that produced by xylidin ponceau.

Echtgrün bläulich produces a tone midway between blue and green, which corresponds to about b<sub>1</sub> F.

Methylene blue stains a blue with a faint greenish shade, which is complementary to the orange of the D line. This colour corresponds to Paris blue.

Höchst Neublau stains a purer blue, which almost corresponds to ultramarine, but in comparison with this, which must be called a pure blue, is slightly greenish.

The various dyes belonging to the eosine group produce bluish-red tones, and can be used in neutral solution. The ordinary so-called yellowish eosine stains a pure red, similar to carmine, whilst erythrosine gives a red colour with strong blue tinge or a purple colour.

By mixing these dyes gelatine films may be stained in any colour, and, as an example, we may quote the light-filters already described.

The colour imparted to the gelatine almost always alters in drying the picture; the red colours become bluer, and the blue greener. Thus, for instance, a film coloured with echtgrün bläulich, whilst still wet, is a peacock blue colour, corresponding to the spectrum line F, whilst when dry a blue green, which lies nearer the green between b and F, is formed.

Almost all organic dyes exhibit the peculiarity that with increasing concentration they become mixed with red, therefore a gelatine picture coloured with erythrosine appears almost pure red in the shadows, whilst the lights shade off into purple. With a blue-stained picture the shadows show less of a greenish tinge, and a yellow picture shows the deepest shadows orange. For these reasons all the deep shadows generally appear reddish in transparent three-colour pictures; a dark blue velvet drapery, for instance, shows in the folds reddish-brown instead of black shadows. This fault is only recognisable, however, with intense illumination of the picture, for with a light that is not too bright the deep shadows appear opaque, and therefore black.

For colouring the three gelatine images obtained as described above the following solutions may be used:—

For the red—	
Water.....	100 c. c.
Alcohol.....	30 "
Erythrosine solution (1 : 200) .....	5 "
For the blue—	
Water.....	100 "
Alcohol.....	30 "
Echtgrün bläulich * solution (1 : 200) .....	15 "
Methylene blue " (1 : 200) .....	2 "
Glacial acetic acid .....	10 drops.
For the yellow—	
Water.....	100 c. c.
Alcohol.....	30 "
Naphthol yellow SL.† (1 : 200) .....	10 "
Methyl orange (1 : 200) .....	10 "
Glacial acetic acid .....	10 drops.

The picture to be coloured should be laid in a dish and flowed over with the dye solution and allowed to remain till it is saturated with colour, which will take about half an hour. It should then be removed, allowed to drain well, and then placed in the following washing solution:—

Water.....	100 c. c.
Alcohol.....	80 "
Glacial acetic acid .....	80 drops.

If celluloid films are used there should be added also—

Glycerine .....	10 c. c.
-----------------	----------

in order to keep the films supple after drying. This solution removes all the dye which has not combined with the gelatine without weakening the colour.

The pictures should be left in the washing water for one or two minutes, and then allowed to dry.

If the high lights of the picture, which should be white, appear stained, they may be cleared by treating with water. The picture should be placed in a dish filled with water, and allowed to remain, with constant rocking, till the lights when looked through appear white, and then it should be transferred to the above washing solution in order to stop the reducing action of the water. If it is desired to weaken the picture very much or to completely decolourise it, a few drops of ammonia should be added to the water.

By alternate treatment with the solution of dye and with water and ammonia, the shading may be varied within tolerably wide limits, the picture may be coloured "hard" or "soft," and thus compensate to some extent for differences in the negatives, and for small faults in the time of printing and preparing the gelatine prints.

If the negatives were too dense or printed too long, it is not easy to

obtain sufficiently modelled shadows. It is advisable, therefore, in such a case, to more than saturate with colour by leaving the picture in the dye solution for a long time, then to treat with water till the bright half-tones are decolourised, and finally to again stain for a short time.

If the coloured pictures are superimposed when dry, the result is rarely satisfactory, and it is almost always necessary to correct one or other of the pictures by clearing, reducing, and restraining as above described.

#### *The Superposition of the Separate Pictures.*

For the final combining of the celluloid films, a resin solution is required, but it must be noted that alcohol, benzole, chloroform, or ether, cannot be used, because these liquids soften and deform the films. The best thing to use is a solution of Canada balsam in petroleum benzine (1 : 1).

The blue print should be laid on a sheet of glass with the film side away from it, and the edges fastened down with strips of gummed paper; then, by the aid of a soft camel's-hair pencil, the balsam solution should be spread over it tolerably thickly, and on this should be laid the yellow picture, which should also have been coated with the solution, avoiding, of course, air bubbles, and the latter shifted till the outlines of the two pictures absolutely coincide; and a magnifier will be useful at this point. Then the position of the yellow print should be fixed with strips of gummed paper, and the red picture cemented down in the same way.

After some hours the edges of the combined picture should be cut and placed on a sheet of glass in the correct position for the stereoscope, a cover glass put over the same, and the edges bound with binding strips.

The Canada balsam between the films dries very slowly; but this is of no moment, as the pictures are not exposed to a high temperature.

The combination of the mica lantern pictures is effected without any medium, merely by superposition and binding with gummed paper. In one corner of the glass picture should be placed a small piece of wax, the mica picture should be placed on this, and shifted till the outlines coincide, and the position fixed by means of gummed strips of tissue paper. The wax is only used to temporarily hold the two pictures together. In a similar way the second glass picture is now fitted, and the whole fastened together at the edges by gummed binding strips.

#### *C.—Other Methods for the Preparation of Three-colour Transparencies.*

1. Very meagre details have, up to the present, been given of Dr. Sells's process. A glass plate is coated with collodion, and on the film thus formed, which gives the actual image-bearing film, a gelatine solution mixed with a bichromate is poured, and allowed to run off. When dry it is printed under a negative, washed in cold water, and the plate placed in the solution of a dye which is only absorbed by those places which are altered by the action of light. The oxide of chromium formed should act as a mordant and hold the dye fast. After drying, the collodion skins carrying the coloured pictures are stripped from the glass, and bound together by a sticky material.

The process is especially simple, and makes the formation of pictures of absolutely identical size, so that the images at once coincide. It appears, however, that vigorously printed proofs are very difficult to obtain in this way, because the behaviour of the exposed and unexposed chromate gelatine differs so slightly towards dyes.

It is also questionable whether this difference in behaviour of the exposed and unexposed places towards the dye solutions can actually be ascribed to the action of the oxide of chromium. We understand by mordants in dyeing materials that they possess the power of combining with the dye, of taking up the dye and forming with it an insoluble compound. Cotton or linen fibres cannot be dyed by immersion in solutions of dyes; therefore they are mordanted—that is, they are impregnated with iron, aluminium, or chromium oxide; thus bodies are placed in the fibres, which combine with the dyes to form the so-called lakes.

But gelatine does not require a mordant in this sense; it takes up, as has already been mentioned above, most of the dyes without any hesitation, and can itself also, like albumen, be used as a mordant. From some experiments made in order to clear up this behaviour, it appears that the possibility of Sells's process is to be ascribed not to the mordant action of the oxide of chromium, but to the difference in the swelling power of exposed and of unaltered gelatine.

The unexposed gelatine is, to a certain extent, permeable by liquids, whilst the gelatine tanned by light which has lost its power of absorbing aqueous solutions will not permit of the penetration of liquids. If dry gelatine films are treated with solutions of dyes, the film tanned by the oxide of chromium will be coloured more slowly, because the liquid only penetrates slowly. If, however, the unaltered film has been previously allowed to swell in water, it takes the dye slower than the tanned film, because the absorbed water prevents the penetration of the solution. If the coloured films are then treated with water, the unchanged gelatine gives up its dye more quickly than that exposed with the chromate, because the latter can scarcely be penetrated by the water.

By treatment of the still wet gelatine print with dye solution and subsequent washing, a coloured picture can be obtained.

2. *Lumière's Process.*—If a bichromated gelatine film on glass, paper, &c., be exposed under a half-tone negative, a useful image cannot be developed with warm water, because the insoluble part which lies on the

\* Obtained from the Farbenfabrik vormals Friedrich Bayer & Co., Elberfeld.

† Obtained from the Aktiengesellschaft für Chemische Industrie, Basle.

surface of the gelatine film will wash away. If, however, there be added to the gelatine a body in a fine state of division, and only a thin film be used, half-tone positives may be obtained. The possibility of this is now generally known by the gum-bichromate process, which is used by many. A mixture of gum bichromate, a colour in powder, is spread in a thin film on paper, then printed under a negative, and developed by washing with water.

Very similar is the method for preparing colourless gelatine images introduced by Lumière, only in place of a colour, silver bromide is used, which is removed after development by a solution of hypo.

In the patent specification of this process only general statements are found, according to which one can proceed in the following way: A sheet of glass is first coated with collodion, and then coated with a solution of gelatine, gum, fish glue, and so on, to which a chromate and some silver bromide has been added, and allowed to drain, so that only a very thin film is formed on the collodion skin. When dry it is printed under a negative, developed with warm or cold water, according to the solubility of the substance chosen, the silver bromide removed by hypo, then it is washed with water, and finally the transparent picture dyed with the solution of an aniline dye. After drying with the image on, it can be stripped from the glass plate.

The author, however, has not been able to succeed in obtaining satisfactory results in this way. If the reproduction of the half-tones is better than with the gum-bichromate process, because finely divided silver-bromide emulsion is used, and not a heavy colour powder, as in the latter, the pictures are, however, imperfect, and the transition to pure white coarse and abrupt.

Moreover, Lumière does not prepare three separate pictures and then superimpose them, but prints the three negatives one on top of the other in the correct colour. There is laid thus on a suitable support, such as a sheet of glass, first a gelatine film containing silver bromide, to which a red dye has been added. This is then printed under the corresponding negative and developed with water. The red positive thus obtained is then, after drying, coated with collodion or some other insulating medium, and on this another chromated gelatine film, which contains the blue dye, is poured. It is now exposed under the second negative, the blue picture developed, insulated with collodion, coated with a chromated gelatine film containing the yellow dye, and the third negative printed. After development, a finished three-colour picture should be the result.

As will be seen, this procedure coincides exactly with the trichromatic gum-bichromate process, and whoever has tried this will certainly doubt the utility of this method. Even if the chromated silver-bromide gelatine film will give faultless half-tone pictures, it is hardly possible to obtain in this way absolutely satisfactory constituent pictures, since their character is considerably influenced by the time of printing and the process of development. The printing of the one over the other of the pictures with absolutely coincident outlines can hardly be obtained.

The coloured stereo and lantern transparencies placed on the market by Lumière, which are the best which have hitherto been given by the indirect process of photography in natural colours, can scarcely be produced in this way. The extraordinarily high relief of the picture, as well as the easily seen mountant between the three individual pictures, speaks against this. These pictures are probably produced by means of the Woodbury process, a process which may be used with advantage if a large number of coloured pictures from the same negative are required.

3. *The Preparation of the Separate Picture by the Woodbury Process.*—In the process just described the colouring of the three individual pictures must always be separately estimated, and, as has already been mentioned, a subsequent colouration or reduction of the picture is almost always necessary in order to obtain a satisfactory final result. The process is tedious, and therefore less suitable for the preparation of a large number of similar pictures. The Woodbury process presents, on the other hand, the possibility of producing any desired number of equal constituent pictures in a comparatively simple way. The three negatives give, in the usual way, by forming the gelatine reliefs, the Woodbury printing plates, from which proofs on transparent films, such as collodion skins, can be prepared with red, yellow, and greenish-blue gelatine. The intensity of the colour which must be given to the gelatine solution used for the printing must be determined by experiments. If this be done, there ought to be no difficulty in making any number of tolerably equal pulls.

The constituent pictures thus obtained may be fastened together by any suitable mountant.

As has already been mentioned at the beginning, very much better results can be obtained by the above-described methods than by three-colour printing. In the execution of the latter we want the brilliant pure printing inks, and, moreover, the printing plates always show more or less considerable variations from the gradation of the negative, through which very troublesome faults in the reproduction of colours occur. The three-colour transparencies, on the other hand, are formed by a simple copying process, and the process of colouring gives opportunities to correct the gradation in a suitable way.

Obviously, however, a certain discretion is introduced into the process; but this exists in all photographic and photo-mechanical processes.

Every operation must be performed with manual skill, and with the idea of what is to be aimed for, and almost always retouching is necessary to correct the mechanical part of the process.

This will always be associated with photography, and it is quite unfair to expect a reproduction true to the original by colour photography, which cannot be found in a monochromatic photographic picture.

We know that a faultless photographic reproduction of a grey in a picture painted in grey is scarcely attainable, and we are satisfied with a copy which corresponds on the whole with the original without noticing the defective units in the gradation. This concession must also always be made in colour photography. Here also we ought not to require an absolutely truthfulness of colour rendering, but must content ourselves with a picture whose colouring corresponds, on the whole, with the original without insisting on an exact test of its absolute correctness.

## CARRIERS AND CUT FILMS.

At first starting one might well say that there is now no necessity to sing the praises of films—cut films, that is. But the fact is, many workers look at them with something akin to timidity. We can show them some marvellously fine results (for the films of 1899 are more than ten years better than the films of 1889), but there are still many who hesitate.

The price is largely to blame for this; besides which, in order to work them with the most comfort, certain extra appliances are essential. Of course, they may be dispensed with by the more experienced worker, but I am speaking now of labour-saving contrivances, such as film "lifters," "clips," and "hangers," the sort of accessory which our friend Mr. Tylar delights in making; many people would consider these as distinctly necessities and object to the expense of them; added to the extra cost of films (fifty to seventy-five per cent. over the cost of plates) it means a considerable increase in one's yearly outlay, when, from the strictly amateur point of view, there is nothing to be put down to the credit side of the account.

I have for some weeks been using a magazine camera, fitted with carriers for plates or films, a very convenient and satisfactory arrangement. I regret it is not allowable to mention names here, but surely there could be nothing simpler in the way of a changing system. The advantage of being able to use plates or films indiscriminately is no small one.

Film carriers are made practically on the same lines as those for plates, only about half the thickness. Now, when using plates there is (in this camera) little or no risk of jamming, because the glass being of a certain weight will always keep its place. With films, on the other hand, if the camera (as it must often be) is subjected to much vibration, there is a possibility of one or more films rising, or being shaken above the proper level, and thus causing a block in the routine of changing, and, worse still, the film cannot be coaxed back into its place by gentle tapping, as would the plate; in fact, the more vibration, the worse the block, and when this occurs there is nothing for it but to cease operations until the recalcitrant film has been, in an extemporised (or other) dark room, put in its place. It is only necessary once to go through such an experience to start one on the track for a remedy—in other words, we want some simple means of fixing the film in the carrier to entirely prevent any movement in the vertical direction. I tried small discs of gelatine and gummed paper, and small clips made of aluminium, but finally took to the following method: Each carrier has a small hole drilled at the top, the hole ( $\frac{1}{16}$  inch diameter) to be visible when a film is properly inserted, and drilled from the back so as to leave a thin turned-up edge of metal on the face of carrier, which edge is in itself a safeguard, if we can rely upon the film being quite flat. As, however, this is not invariably the case, I make the film more secure by a small plug of wax, which overlaps the top edge of film to a small extent, and is pressed through the hole level with the surface of metal—the hole, being slightly under-cut, holds the wax firmly, and, the carriers being drilled alternately to right and left, no two wax plugs need touch; a very small piece of beeswax (readily softened in the hand)—paraffin wax would be better and harder—serves the purpose. I may interpolate a word of advice here to those who may use these "plate-and-film" carriers, and that is, if on tour and working films, do not on this account leave the plate carriers at home; it may happen, and accidents and other untoward events may occur, that we are stranded somewhere and no more films to be had, whereas every dealer keeps plates. I had the whole of a lovely day wasted recently because of this neglect—a packet of films lost on the way, missed when too late, no more films to be had; plenty of plates, but no carriers to put them in!

In practice it is by no means indispensable to have lifters and other frames for holding the films during development. Having by adjustment of stops and regulation of shutter got approximately even exposures, it is a common practice with me to develop four quarter-plates at a time in a whole-plate tray. They are, even in a special four-division tray, inclined to float one over the other unless special precautions are taken, and having several dozens of films to treat, the difficulty was overcome by first drilling holes in the ebonite tray and inserting wooden plugs to mark the divisions; divide the tray with rule and pencil into four equal parts, then drill

holes ( $\frac{1}{16}$  inch or so), four in the longer line, equidistant, and two in the shorter line at about one and a half inches from the sides. Now put in plugs, which should stand up half-an-inch or so, and be, of course, level on the under side. These little uprights effectively prevent the films from floating one over the other, or overlapping during the necessary rocking of the dish during development. At the same time, the solutions will flow uninterruptedly in any direction. An ebonite tray is by no means spoilt by being treated in this way, as the holes can be readily and effectively plugged with wax, and no one be the wiser. With deeper dishes and more solution there is very little risk of damage to these films by abrasion, even when they are allowed to lie one over the other—ordinary care being used, of course, to remove them from the top layers, and if placed back to back, the usual troughs and racks will be a great help to perfect washing. When we come to the risky operation of drying, we find the small metal clips extremely serviceable and helpful.

J. PRIKE.

### AN IMPROVED MICRO-STEREOSCOPIC CAMERA.

[Paper read before the Photographic and Microscopic Branch of the Franklin Institute.]

I HAVE pleasure in showing you this evening a new camera which I have constructed for the purpose of making stereoscopic pictures of small objects.

To accomplish this end has taken much time and a great amount of experimenting. I first fitted up my stereoscopic camera for the purpose, but the result was not at all satisfactory, although I made some very fair negatives with it. The camera proved to be altogether too short, and the lens and object had to be changed from one side to the other, all of which made it very inconvenient. My next attempt is embodied in the instrument I have here this evening for exhibition. It was originally one of Anthony's lantern-slide cameras, which I have altered to what you now see. The shutter used is a 4×5 "Victor," made by the Bausch & Lomb Optical Company, of Rochester, N.Y. To the front of this I have fitted an attachment to carry the lens, and also to hold a reflector for properly illuminating the object. In the rear of shutter I have, instead of a lens, a ring, to cut off deflected light that might be caused in its passage through the shutter. The rear end of the camera has been fitted up to receive a 5×7 plate-holder, but in such a way that it may be used in two positions, so that each end of the plate may be exposed independently of the other. The plate-holder rests against a partition with an opening in it of a size just sufficient to cover one half of the plate.

The lenses for very small objects are achromatic objectives that are used in the microscope, but for this work are changed somewhat, to better answer the requirements. The trouble I found with them for this work was their narrow angle and extremely small depth of focus, and both of these faults had to be remedied before I found it possible to make a satisfactory negative.

I also found that the rays of light, in passing through the lens, had a tendency to fog the plate by coming in contact with flat surfaces, even when these were blacked with the greatest care. I overcame this trouble satisfactorily by dispensing with the flat surface, i.e., by making them on a bevel, with only the sharp edge to reflect the light. To do away with the difficulty arising from the small depth of focus, the only way was to stop down the lens.

Now, as the depth of some objects is very great in proportion to the focal length of the lens, I was compelled to use a very small stop. (I use the word "stop," as I understand it to mean an aperture placed close as possible to the lens.) The smallest stop I use is  $\frac{1}{16}$  of an inch in diameter, with the edges of the opening made very nearly sharp and carefully blacked. The rear of the lens has also to be guarded to prevent deflections, which in this work would be very serious.

Of course, the time of exposure requires to be lengthened in proportion to the size of stop; the smallest stop sometimes requires as much as forty-five minutes, and as each exposure must be separately made on the plate, the time will be doubled, making for the two exposures ninety minutes.

Now, in regard to the object to be photographed. Let us suppose it to be a small insect. I place it in a bottle containing cyanide of potassium, which soon ends its life; I then set it up on its feet, in a position as nearly life-like as I can, on a small piece of opal glass, and, to hold it in position, I fasten each of its feet down by means of wax; this is done by using a very small tool, heated in the flame of a spirit lamp. After the feet are fastened properly, the surplus wax is carefully removed by scraping it away with a fine-pointed knife. The object now is ready for the camera, and upon the pedestal in front of the lens the mounted object is made fast. Now, this pedestal, upon which the mounted object is fastened, has a rack-and-pinion movement, so as to elevate the object to the required height, and has also a ball-and-socket joint on the top, so that the object can be placed in any desired position. The image on the focussing-glass is brought in position horizontally, by sliding the lens and board, which can be done by turning the milled head on the top of the camera.

Now, to make the exposure. After everything is ready, I place the object in its best position, and focus as sharply as possible, with the image in its proper place on the ground glass. On the front end of the

camera, at the bottom of the pedestal, is a small milled-head screw, which should be turned until it brings up against the shoulder under the camera. This arrangement is for the purpose of permitting the removal of the lens from the object, and its return again to exactly the same place, so that there may be room to change the stops. The reason for doing this is that, after the small stop is in place, it is impossible to see any image whatever on the ground glass.

Now I fasten front and rear of camera (after the proper stop has been put in place) by means of the clamp screws at the side, and run in the plate-holder until it drops into the first groove, then set the camera in position with the reflector facing a northern sky, and make the first exposure.

After the first exposure is made, the stop is removed, and upon the pedestal will be found a graduated circle, divided into parts of 5° each, and also a pointer. This pointer is now to be moved round one of the graduations from left to right, and then the image on the ground glass again placed in position. The stop is put in place, plate-holder is returned and run back as far as possible until it drops into the second groove, and the exposure repeated for the other end of the plate. By revolving the object in the direction just mentioned, the negative itself is made stereoscopic, and can be placed in the 'scope and examined to see if it is perfect.

For objects that are nearly the full size of the picture wanted, I use a pair of wide-angle 4×5 lenses.

JOHN G. BAKER.

### TRANSFERRING KODAK FILMS.

[Journal of the Photographic Society of Philadelphia.]

ABOUT two years ago I loaded up my Kodak with 100 exposures, and spent the day at Hampstead Heath, on "Bank Holiday," snap-shooting "Arty and Arriet," the costermonger and his girl. The films developed all right, yielding negatives of fine quality, but upon drying I found them suffering from smallpox, peppered entirely over with opaque spots. Examination revealed the fact that the damage was caused by the surface of the celluloid next to the film being covered with chalk dust. The films were returned to the Kodak Company, attention called to the trouble, and a request made that, if possible, the films be transferred to clear celluloid. They were returned, two only being transferred, apparently to the surface of a piece of transparent tripe. Wishing if possible to save these negatives, I made various attempts to strip off the film and transfer it to glass, and at length succeeded so well that I am now at work turning all my films into plates. The method is simplicity itself:—

Dip the film for a few moments in a 10 per cent. solution of alum. This has a tendency to contract the upper surface of the gelatine. Now lay the film on a sheet of glass, and with the fingers rub back the gelatine coating, beginning at the upper corners and working from side to side, until the film rolls off like a cigarette. This is placed in running cold water, to take out the alum, then dipped for a few minutes in a 10 per cent. solution of glycerine and water, the object being to prevent the film from peeling from the glass when dry. For a 4×5 film I use a 5×7 sheet of glass. This is placed under the stripped film in a tray of clean water, the plate lifted, the film caught, and put under running water, which immediately flattens out the film and drives out air-bubbles. Any wrinkles may be smoothed out with the fingers. When the transferred film dries, it is in all respects equal to any glass negative, all the objectionable grain being left in the celluloid. Moreover, the transferred negative may be intensified or reduced, exactly as if it had always been on a glass support. The joint in the celluloid always comes in the middle of a film negative, but, when transferred, no sign of a joint is visible.

After exposing and transferring about 300 negatives, I have come to the conclusion that the operation entails far less labour than the carrying of glass plates in the field and the bother of plate-changing.

WILLIAM N. JENNINGS.

### THE NATIONAL PHYSICAL LABORATORY.

THE realisation of the scheme for the establishment of a National Physical Laboratory, says *Nature*, is primarily due to two addresses delivered before the British Association in 1891 and 1895 by Professor Oliver Lodge and the late Sir Douglas Galton respectively. The fact that Sir Douglas Galton, when President of the Association, did all in his power to support the proposal originally made by Professor Lodge led to the matter being laid before the Prime Minister by a strong deputation. A Committee, of which Lord Rayleigh was Chairman, was then appointed by the Treasury, and, after taking evidence, reported in favour of the establishment of a public institution for standardising and verifying instruments, for testing materials, and for the determination of physical constants. They further recommended that the institution should be established by extending the Kew Observatory in the Old Deer Park, Richmond, and that the Royal Society should be invited to control it and to nominate a governing body, on which commercial interests should be represented, the choice of the members of such body not being confined to Fellows of the Society.

These recommendations were approved, and, to give effect to them, the Government undertook to ask Parliament for 12,000*l.* for buildings and for 4000*l.* a year. A scheme for the management of the new insti-

tution has been approved by the Treasury, and the first instalment of the promised grants has been sanctioned by the Legislature. The Kew Observatory Committee are willing that the Institution which they have managed very successfully should be merged in the National Physical Laboratory, which will thus become possessed of an endowment of 458*l.* per annum from the Gassiot Trust and of an income of about 2700*l.* from fees for standardising. The receipts have, in the past, rather more than covered the expenses of carrying on the work of the Observatory.

The ultimate control of the National Physical Laboratory is placed in the hands of the Royal Society, but the constitution of the bodies which manage it directly can only be altered with the consent of the Treasury. These are an Executive Committee and a General Board. The latter is a relatively large body, to which the Executive Committee must report annually, and to which it must submit its scheme of work for the next year. An essential feature in the constitution of the General Board is that twelve of its members are nominated by six of the great technical societies, viz., the Institutions of Civil, Mechanical, Electrical, and Naval Engineers, the Iron and Steel Institute, and the Society of Chemical Industry. Six of these representatives of "commercial interests" are also to be members of the Executive Committee, which will ultimately consist of twelve ordinary and five official members, of whom the latter are: the President of the Royal Society, the Chairman of the Committee, the Permanent Secretary of the Board of Trade, and the Treasurer and one of the Secretaries of the Royal Society. In the first instance, six members of the existing Kew Observatory Committee will also have seats on the Executive Committee, but their places will not be filled up when their period of office expires. Finally, it is in the power of the Executive Committee to appoint sub-committees to superintend particular departments or investigations. The members of these sub-committees need not necessarily be members either of the General Board or of the Executive Committee.

Preliminary arrangements have been in progress for some time in order that the National Physical Laboratory should be organized as soon as possible after the requisite funds were voted by Parliament.

The six technical societies have nominated their representatives, the General Board and Executive Committee have been constituted, and general satisfaction will be felt at the announcement that Lord Rayleigh has accepted the Chairmanship of those bodies.

On the recommendation of the Executive Committee, the Council of the Royal Society has appointed Mr. R. T. Glazebrook, F.R.S., now Principal of University College, Liverpool, to the important post of Director of the National Physical Laboratory. A number of sub-committees have also been organized by the Executive Committee, which have been requested to make suggestions preparatory to the drawing up of a detailed scheme of work and of the plans of the new buildings.

The members of the Executive Committee are:—

Lord Lister, P.R.S., Lord Rayleigh (chairman), Mr. A. B. Kempe, Treas. R.S., Professor A. W. Rüchker, Sec. R.S., and Sir Courtenay Boyle (*ex officio*), Captain W. de W. Abney, Sir N. Barnaby, Mr. G. Beilby, Sir E. H. Carbutt, Bart., Captain E. W. Creak, R.N., Professor R. B. Clifton, Professor G. C. Foster, Mr. F. Galton, Professor O. J. Lodge, Sir A. Noble, Professor J. Perry, Sir W. Roberts-Austen, Professor A. Schuster, Mr. A. Siemens, General Sir R. Strachey, Professor J. J. Thomson, Dr. T. E. Thorpe, Sir J. Wolfe Barry.

In addition to the above the following are also members of the General Board:—

Sir M. Foster, Sec. R.S. (*ex officio*), Sir F. A. Abel, Bart., Professor W. G. Adams, Professor W. E. Ayrton, Mr. H. Bell, Mr. A. Buchan, Mr. B. E. Crompton, Professor G. F. Fitzgerald, Professor J. Joly, Lord Kelvin, Mr. J. T. Milton, Sir W. H. Preece, Mr. W. F. Reid, the Earl of Rosse, Dr. B. H. Scott, Mr. W. N. Shaw, Mr. C. E. Stromeyer, Admiral Sir W. Wharton, Sir W. H. White.

The following have also been requested to serve on one or other of the sub-committees above referred to:—

Messrs. E. D. Archibald, C. V. Boys, Professor H. L. Callendar, Messrs. Forbes Carpenter, W. H. M. Christie, T. B. Dalmeyer, Professor J. A. Ewing, Mr. S. Z. de Ferrant, Professor J. A. Fleming, Messrs. R. E. Froude, E. H. Griffiths, J. Mansergh, T. Matthews, W. H. Maw, Dr. L. Mond, the Hon. C. A. Parsons, Professor A. W. Reinold, Captain H. B. Sankey, Messrs. J. Swinburne, G. J. Symons, H. A. Taylor, Professor S. P. Thompson, Messrs. J. I. Thornycroft, C. H. Wordingham, and A. F. Yarrow.

It will thus be seen that the National Physical Laboratory is being founded on a wide basis. A definite scheme of work will be arranged during the autumn. The Director will, it is hoped, take up the duties of his office on January 1, 1900, and the planning and erection of the new buildings will then proceed with as little delay as possible.

#### PHOTOGRAPHY AND FOUR AT A BIRTH.

At the Sunderland County Court, last week, a novel case was heard by Judge Greenwell. John George Dixon and his wife, Agnes Annie, were the plaintiffs, and Dr. H. De Wytt the defendant. Mr. A. G. Boulton appeared for the plaintiffs, and Mr. J. T. Green for the defendant.

Mr. Boulton said that the plaintiffs claimed the delivery of six photographs promised to them by defendant or 15*l.*, together with 5*l.* for the trouble and the annoyance and risk that they had been put to by the defendant.

Agnes Annie Dixon said her husband was a draper, and they lived at 21, Smith-street, Ryhope. On May 31 last, she gave birth to four children—three boys and a girl—and she was attended by the defendant, who was assistant to Dr. Robinson. After the birth of the children defendant remarked that it was a remarkable case, and the like had never taken place in Ryhope, and that in all probability it would never occur again. He, therefore, suggested that the children should be photographed at once, as he thought they would not live long. Defendant pressed his request by pointing out that the photograph would be the only thing they would ever have to remember the children by, and that if witness did not possess a photograph of them, no one would ever believe that she had had four at a birth. He further agreed to give her half-a-dozen of the photos for herself. Under his persuasion she consented to have the children photographed. Defendant instructed the photographer, and with the children artistically arranged in an arm-chair and upon the table in the room where witness was lying the photos were taken. Next day defendant returned, and said that, in consequence of one of the babies having moved, the photos had been slightly "smudged." He therefore suggested that it would be better to have a perfect copy "when they were about it," and asked her to let the photographer take another one. Witness's husband was perfectly willing, provided witness's health would not be endangered. Defendant again promised to give them half-a-dozen of the best, and they consented to give the photographer another sitting. Witness felt the strain very much, and went into a delirium. The children had since died. Some time afterwards, they learned that the photos were being shown in the village. Her husband thought this strange, and he asked defendant when they were going to get them. Defendant replied that he was sorry, but the photographer had destroyed the negative, and he was therefore unable to fulfil his promise.

Cross-examined by Mr. Green, witness denied that her husband ever wanted to enter into a contract with the photographer to supply him with a number of photos so that he might sell them. The explanation was that a very large number of their acquaintances asked them for photographs, and as they were unable to buy each of them one, they agreed to get them one, providing they were willing to pay for them. She knew the negative was being copyrighted.

John George Dixon, husband of the last witness, corroborated, and said he never had any idea of making money out of the photographs. The very idea was repugnant to him.

Dr. Wytt, the defendant, admitted arranging for the children to be photographed, and denied ever having promised to give the parents half-a-dozen copies. As a matter of courtesy, he promised to give them a copy.

Under cross-examination, witness said that the negatives were not destroyed, they were in his possession. He considered that the sale of the photographs would be a reflection upon his professional conduct.

The Judge: How?

Witness: It was a surgical case.

The Judge: Supposing it was, it does not touch the point.

Mrs. Dixon: Yes, and you've got a photograph of them hanging in your surgery.

Wm. Sheraton Hogg, photographer, Ryhope, deposed to taking the photographs. Acting upon the defendant's instructions he refused to give any one a copy.

His Honour found for plaintiff for six guineas, to be reduced to a shilling if six copies of the photographs were delivered within seven days.

Mr. Boulton asked his Honour to make a simple order for the delivery of six copies of the photographs.

After a legal argument his Honour said he did not see any reason why the plaintiffs should not have the photographs; he therefore found for them for 15*l.*, to be reduced to a shilling if six copies of the second day's photograph were delivered within fourteen days.

## Our Editorial Table.

We have received from Mr. A. A. C. Swinton a reprint of the paper on *Electric Discharges in Vacuo and the Röntgen Rays*, which he read before the Philosophical Society of Glasgow on March 1 last.

#### CATALOGUES RECEIVED.

York & Sons, 67, Lancaster-road, Notting Hill, W.

MESSRS. YORK send us their thirtieth annual Supplemental Catalogue of lantern slides, lecture sets, &c. Cairo, Palestine, Jerusalem, Shakespeare's Avon, Berlin and Dresden, Human Vision, Sicily, Cromwell, are among the subjects of the lantern slide sets.

Thomas Illingworth & Co., The Photograph Works, Rucklidge-avenue, Willesden Junction, N.W.

MESSRS. ILLINGWORTH'S Catalogue deals with the firm's specialities in enlarging, finishing, printing, &c. Carbon effects at bromide prices are given prominent mention.

## News and Notes.

PHOTOGRAPHIC CLUB.—August 30. Open Meeting.

THE Annual Exhibition of the Ludlow Photographic Society will be held in the Assembly Rooms, Ludlow, on Wednesday, October 11.

THE following gentlemen have consented to act as judges at the Annual Exhibition held on November 15, 16, and 17, at Morley Hall: Messrs. J. B. B. Wellington, Horsley Hinton, and Harold Baker.

THE yacht *Shamrock* has gone out to America armed with a Lizar's Challenge half-plate focal plane camera. To ensure the best results being had from the negatives, they are, after exposure, to be immediately sent over to this country for development.

VANISHING OLD LONDON.—The old house opposite the Métropole Theatre, Camberwell, and familiar to South Londoners of past generations as the Eel Pie House, the Haunted House, and the Greyhound, which was the object of a visit by the members of the Archaeological Society some time ago, is being demolished. Four shops are to be erected on the site.

THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.—At the last meeting of the Council of the National Photographic Association, the President (Sir J. Benjamin Stone, M.P.) in the chair, 185 photographs were presented, taken by Messrs. B. Diver, Basil E. Lawrence, E. Scamell, and George Scamell (Hon. Secretary). The subjects included Elgin Cathedral, some of the old houses in and around London, Waltham Abbey, and the churches and monuments at Hendon, Ickenham, Wheatthampstead, Biggleswade, Sandridge, St. Luke's, Chelsea, &c. These will be forwarded immediately to be added to the collection at the British Museum.

"THE distinguished thing at present," says a writer in the *Referee*, "is not to have your photograph in the papers, not to be interviewed. The illustrated papers and the trashy magazines have done for that. There was a time when a 'smart' lady would have paid anything to get her photograph or the photograph of her pet dog into the papers, but they want something more than that for their money now, I can tell you. A series of photographs of the interior of your house, or a picture of yourself and your parents and your offspring? Nothing in that any longer. Even the pictures of the Finger-nails of Celebrities and the Noses of Eminent People, and all that sort of thing, must come to an end, and what the magazines are going to do then, I'm sure I don't know."

THE latest discovery in America is a boy with such peculiar vision that he can see through substances in the same way as the Röntgen rays. His name is given as Alvey Leonel Brett, of South Braintree, Mass. The boy is said to have diagnosed a number of fractures. In confirming the diagnosis of a broken hip, he pointed out that the fracture was nearer the head of the bone than had been thought by the physicians. He examined a child who, it was supposed, had swallowed a coin, and declared there was no coin there. This was proved to be correct at the post-mortem, the child having died from other causes. The lad also used this power by so concentrating the sight as to shut out ordinary daylight. The air, he says, is then filled with flashes of a pale greenish light, which illuminates the object to be examined. This light, he says, is the same as the X ray in the Crookes tube. Daylight is then darkness, or a reddish black.

THE SANDELL "PERFECT" COMPETITION.—The July awards in this competition were as follows:—10l. prize, three studies—*The Blacksmith*, *The Blacksmith's Shop*, *The Village Smithy*. Mr. Arthur Waterall, Flixton, Lancashire; 5l. prize, *Does he come?* Mr. C. F. Inston, Liverpool; 1l. prizes, *A Shadow on the Path*, Miss Agnes B. Warburg, London; three studies—*Reaper of the Sea*, *Outboard Bound*, *Evening*, Mr. William Norrie, Fraserburgh, N.B.; *Lilies*, Miss Simmonds, Bromley, Kent; *Cloisters*, Gloucester Cathedral, Mr. H. C. Leat, Bristol; *Interior of St. Mary's Church*, Balham, Mr. A. E. Walsham, Balham; three studies—*Off to the West*, *After Sunset*, *Before the Storm*, Mr. G. H. Gidman, Liverpool; *Knights of the Glen*, Mr. R. Stockdale, Leeds; *Two Interiors with Figure*, Mr. C. S. Tyler, Earls Colne, Essex; two studies—*Young Cuckoo in Meadow*, *Pipit's Nest*, *Homeward Bound*, Mr. G. Graham, Girvan, N.B.; *Household Duties*, Mr. T. Knox, Belfast.

VALUE OF THE SUN'S RAYS.—Professor Sinclair says that many know by experience that the relief afforded by the sun's rays to wearing pain, neuralgic and inflammatory, is more effective and lasting than that of any application whatever. Those who have face-ache should prove it for themselves, sitting in a sunny window, where the warmth falls full on the cheek. For nervous debility and insomnia, the treatment of all others is rest in sunshine. There is no tonic like it, provided the good effects are not neutralised by ill-feeding. To restore a withered arm, a palsied rheumatic limb, or to bring a case of nervous prostration up speedily, a most efficient part of the treatment would be to expose the limb or the person as many hours to direct sunlight as the day would afford. With weak lungs, let the sun fall full on the chest for hours. For the chilliness which causes blue hands and bad colour, resort to the sun; let it almost blister the skin, and the circulation will answer the attraction. It is a finer stimulus than wine, electricity, or massage, and we are on the verge of great therapeutic discoveries concerning it.

THE KODAK WORKS.—The works of Kodak, Limited, at Harrow, were on Saturday afternoon last on the occasion of the visit of the London staff. The visitors, numbering about 150, arrived at Harrow station about three p.m., where they were met by the heads of the factory departments, and conducted over the works in groups. The inspection of all the various departments occupied over two hours, the various processes being minutely explained by the guides, selected from the technical staff. Shortly after the factory closed, the combined staff, numbering over 500, were photographed in one group, and then sat down to tea in a marquee erected in the grounds. After tea, various friendly games and contests were fought out between the Harrow and London staffs. The lawn tennis courts were freely used, and

dancing on the lawns continued until 8.30. The band of the 5th Middlesex Volunteers (by kind permission of Major Harris) furnished the music during the afternoon and evening. The complete success which characterised this friendly gathering of the whole English staff will no doubt lead the directorate of Kodak, Limited, to repeat the experiment at an early date.

WE regret to record the death, under exceptionally sad circumstances, of Mr. J. R. Bourne, an assistant in the employ of Mr. Busbridge, of Blackbeath, who speaks most highly of his abilities and punctuality. Mr. Bourne left business on Saturday evening, August 5, to spend the August holiday at his home in Folkestone, returning to business on Wednesday morning, August 9, in his usual health, and expressing himself as having had an exceptionally enjoyable holiday. He went about his work without showing the least sign of anything amiss until about four o'clock in the afternoon he complained of faintness, which passed away shortly, and he continued work for a while, when the faintness returning necessitated his removal to his apartments, where he passed peacefully away at eleven o'clock the same evening, through apoplexy. His relations were summoned by telegram, but were unable to reach London in time to see the last. Mr. Bourne had endeared himself to many by his thoroughness and kindly disposition, and his loss will be deeply felt. He had previously been in the employ of Messrs. Wing, of Tunbridge Wells; Lord, of Cambridge; and Coles, of Watford.

SUNDAY TRADING.—John Hawkey, Humber-street, Cleethorpes, pleaded not guilty, at the Grimsby Police Court, to pursuing his business as a photographer on the Lord's Day, on August 6, on the Promenade at Cleethorpes. Police-constable Page said that defendant was giving out circulars to passers-by and offering to take their portraits. Defendant said that Sunday was the best day for photographers, and why could they not take photographs in Cleethorpes on a Sunday the same as in other places? The public could not object to it, or why did they take more photographs on Sundays than on two or three days in the week put together? He had been seven years in Blackpool, and never knew what it was to have a Sunday off there. It was as necessary to take portraits on a Sunday as it was to sell tobacco, yet tobaccoists could open on a Sunday. In reply to the Chairman, defendant said he was fined for a similar offence a month ago; but, he added, he was not before the Court out of any spirit of defiance of the law, but to explain to the Bench that he simply exposed the plates on a Sunday and did not finish the photographs. The Chairman said it was trafficking, and defendant would be fined 5s. and costs, 4s. 6d.—Defendant: What if I refuse to pay the money?—The Magistrate's Clerk (Mr. T. Mountain): You will find out.—Defendant paid the money.

A NEW METHOD OF TEACHING DRAWING.—The new methods of art and manual training devised by Mr. J. Liberty Tadd, Director of the Public School of Industrial Art, Philadelphia, formed the subject of an interesting lecture which was given recently by Mr. H. Bloomfield Bare, F.R.I.B.A., in the Lecture Theatre of the College of Art, South Kensington. The most striking point about this training is its ambidextrous character, the child being taught to use both hands alike. The pupil learns first to draw on the blackboard simple curves, circles, and other freehand figures, and goes on with original design and creative drawing, and then to modelling in clay and carving in wood. Mr. Bloomfield Bare's lecture was devoted to a full explanation of the system of blackboard drawing. He had studied Mr. Tadd's system during a five-years' residence in Philadelphia. In drawing on a large scale on the blackboard, the child was taught to exercise its muscles; there was no niggling work, but a free clear stroke was acquired. By the bi-manual training a perfect and equal development of the muscles was obtained. As a practical illustration of what can be accomplished in this way, Mr. Bare's daughter then drew a number of figures and designs upon the blackboard, some being of a very elaborate character, using her left hand for that part of the design that was on the left side quite as easily as her right, and drawing curves and circles on a large scale with wonderful steadiness and accuracy by a single movement of the hand. A number of lantern slides were exhibited, showing photographs of classes of children actually engaged in blackboard drawing.

THE late Professor Bunsen, one of the greatest chemists of his time, was of the same peasant-farmer stock settled in Waldeck which, by a different branch, produced Baron Bunsen, the scholar and diplomatist. His father was a professor of Occidental literature in the Hanoverian University of Göttingen, where he was born in 1811, about two years before Bismarck. Soon after taking his degree he succeeded Wöhler as teacher of chemistry at the Polytechnic Institute of Cassel in 1833, whence in 1838 he was appointed to Marburg as assistant professor of the same science, attaining to the chair thereof in 1841. Ten years later he was called to Breslau, and the following year, 1851, to Heidelberg, on the University of which Bunsen was to shed a new lustre by his brilliant discoveries in the field of practical science. In conjunction with Professor Kirchhoff, of Berlin, Bunsen may be said to have been the founder of stellar chemistry, and his numerous discoveries, from the spectrum analysis down to the simplest manipulations of practical chemistry, soon procured for him a world-wide reputation. Some of our own most distinguished scientists studied under him at Marburg or Heidelberg. Foreign honours rained in on him, and in 1883 he was appointed one of the eight foreign associates of the Paris Academy of Science. Among his numerous discoveries was an antidote to arsenic, and the galvanic battery and photometer which bear his name. His scientific writings would require a catalogue all to themselves. The simplest and most genial of men in private life, Bunsen has left a host of European pupils who will mourn his loss as one of the greatest scientific discoverers and teachers of his time.

THE following is the list of awards of the Warwick Monthly Competition for August:—10l. prize, *Nap*, Mr. A. Coupe, photographer, 43, Wilmstow-road, Manchester; 5l. prize, *Child eating Strawberries*, Mr. S. Lambert Weston, photographer, 23, Sandgate-road, Folkestone; 1l. prizes, *Study of a Rose*, Miss Ellen Blakeley, 5, Weld-road, Birkdale, Southport; *Two Sisters*, Mr. E. W. Bradden, 14, North-street, Guildford; *Child Laughing in the Window*, Mrs.

Josephine E. Cordiner, Naruton Lodge, Great Malvern; *Interior of Tintern Abbey*, Mr. R. W. Dugdale, 25, Kingsholm-road, Gloucester; *Bubwith Church Tower from the West*, Dr. G. A. Farrer, Brighouse, Yorks; *The Last Load*, Mr. J. Willis Grundy, 22, Steven-street, Stretford; *Companions*, Mrs. Holmes, photographer, 4, Park-street, Lytham; *Herd of Jerseys*, Mr. A. E. Horne, Raa, Magistrate, Queenstown, Ireland; *Portrait Figure Study*, Mr. W. G. Jameison, Cults, Aberdeenshire; *The Coast of Sark*, Captain H. G. Kennard, La Casita, Dinard, France; *A Willing Model*, Mr. A. B. Knight, High-street, Knighton, Radnorshire; *The Graveyard in Navvies Prison*, Mr. V. Levi, 20, Princes-square, London, W.; *A Little Girl Knitting*, Mr. J. Peat Millar, Braehead, Beith, Ayrshire; *The Finishing Touches*, Mr. W. Northwood, Wordsley, Stourbridge; *Cadder Water, Duntocher*, Mr. Isaac G. Paterson, Postal Telegraphs, Glasgow; *Orford in Kent*, Mr. Karl Rauch, 41, Chapel-road, West Norwood, S.E.; *Neath the Shade of Ancient Trees*, Mr. A. R. Read, jun., Rothsay, Clifder-road, Brentford; *After the Cycle Parade*, Mr. David Reid, Brighton-avenue, Woodsend-road, Flixton; *An Avoikward Encounter*, Miss Ella Tomlinson, Kensington-cottage, Fishbourne, Chichester; *Children at Lessons*, Mr. C. S. Tyler, High-street, Earls Colne, Essex.

**SECCO FILMS (LIMITED).**—As will be seen by an announcement in our outer pages, Secco Films (British and Colonial) (Limited) has been formed, with a capital of 100,000*l.*, in 1*l.* shares, to acquire the invention of Herr Oswald Moh, of Görlitz, Germany, for improvements in and connected with photographic films (known as Secco films), with the right to apply for and obtain colonial patents and rights for the invention, and to carry on the business of manufacturers and dealers in photographic apparatus and materials. The purchase price has been fixed at 80,000*l.*, payable 30,000*l.* in cash and 16,667*l.* in cash or shares, and the balance in shares. The present issue is of 66,667 shares, of which 20,000 shares will be appropriated to provide working capital, and for the purchase and erection of plant. The list closes on Saturday.

## Patent News.

THE following applications for Patents were made between August 8 and August 12, 1899:—

**PHOTO-ETCHING.**—No. 16,137. "Improvements in the Art of Making Half-tone Plates." J. GIESSECKE.

**PRINTING.**—No. 16,292. "A New or Improved Photographic Printing Process." G. T. HOLLOWAY.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
29.....	Birmingham Photo. Society .....	Demonstration: Messrs. Wellington & Ward's New Negative Film. Harry Wade.
29.....	Hackney .....	Stereoscopic Work. A. D. Fort.
30.....	Kingston-on-Thames .....	Excursion: Windsor. Leader, A. Van-dendriesche.
30.....	Photographic Club .....	Open Meeting.
30.....	West Surrey .....	Affiliation Lecture: Lantern - slide Making. J. A. Hodges, F.R.P.S.
September.		
1.....	Manchester Amateur .....	Carbon Printing. J. H. Evans.
2.....	Borough Polytechnic .....	Excursion: Theydon Bois and Roding Valley. Leader, P. C. Cornford.
2.....	Hackney .....	Excursion: Benfleet and Canvey Island. Leader, J. J. Westcott.
2.....	Manchester Amateur .....	Excursion: Hoylake. Leader, S. L. Coulthurst.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 10.—Mr. T. E. Freshwater in the chair.

The CHAIRMAN gave an anecdotal account of some of the pictures he might have made of bathing scenes at Overstrand, Norfolk, where he had spent his holiday, if he had not left his hand camera at home. From his account the subjects appeared to be much over-exposed.

Mr. Rapson passed round two negatives, which had been exposed in a hand camera. Almost in the centre of each appeared a circular spot, about the size of a shilling, where the negative seemed normal, the other part, including that protected by the rabbit of the plate sheaths, was fogged. Of two dozen plates, exposed under exactly the same circumstances, these two negatives were the only ones showing any defect.

Mr. P. EVERITT suggested as a possible explanation that the two plates had been left at some time in an unsafe light with some circular objects upon them.

The CHAIRMAN, referring to the photographs exhibited for sale at the seaside places he had recently visited, said that those produced in colour, such as those of the photochrome, Zurich, seemed to have quite supplanted the ordinary photographic views.

Mr. RAPSON said he was not surprised at that, if, elsewhere, the local

photographers produced nothing better than the photographs he had seen on sale at Southend and the neighbourhood. These he characterised as being atrocious, both technically and artistically.

Mr. A. MACKIE asked the reason that, with all the new developers, a large amount of sulphite of soda was included in the formula when it seemed not to be requisite? He instanced a recent experience, using a solution of ortol, with half the weight of metabisulphite of potass as a preservative, and a plain solution of carbonate of potass, he had obtained negatives which might be practically described as black.

A long, but quite unreportable, discussion then took place upon the colours of deposit in negatives and development stain, and the effect of a black-and-white and a coloured negative upon the print.

AUGUST 17.—Mr. T. E. Freshwater in the chair.

Mr. W. D. WELFORD mentioned that he had recently been troubled with markings on the films of negatives that had been soaked in an alum bath before fixing.

It was suggested that some of the alum might have remained in the film, and had decomposed the hypo of the fixing bath.

Mr. WELFORD said that this could not have been the case, for the markings were visible before immersion in the fixing bath.

Mr. S. H. FRY, in a discussion which took place on stained negatives, said it was quite a common thing in the course of his business, to have an order to remove stains and other defects from negatives. Recently, his operator having failed to rectify by ordinary means three negatives which had apparently been insufficiently fixed, he had spent two to three hours experimenting with them, but with hardly any result. The difficulty was that, though the negatives after his treatment appeared in fairly good condition, upon drying the shadows became quite opalescent. Mr. Fry also referred to a difficulty in making paper negatives of large size, owing to the tenderness of the paper support. It was impossible to hold up the negatives while wet in the usual way by the corners, as the weight of the sheet was too great.

The CHAIRMAN, referring to some negatives shown at the previous meeting by Mr. Ropson, which showed a circular patch of comparative unsensitiveness about the centre, said the defect had been traced to a piece of leather at the bottom of the camera, placed there to cover the hole where the tripod screw was inserted.

Mr. A. MACKIE said he had tried that day the addition of sulphite of soda to the sulphocyanide mercury bath for the first time. His experiment was with matt P.O.P. He had removed the prints from the toning when quite warm in the shadows by reflected light, and at a stage when, with the ordinary sulphocyanide bath, the shadows would be quite red in the finished print. His finished results were less warm than when they left the toning bath, and there was no appearance of double toning.

Referring to toning bromide prints with alum and hypo, a member said he had never succeeded until he had adopted the method of proceeding in a directly contrary way to the usual instruction. He used a freshly mixed bath; and not a matured one. He found the toning action began when the bath reached a temperature of 115°. He found it unnecessary to raise the temperature much over 120°. To obtain a successful result, it was necessary to have a print not too heavy in the shadows, or it was impossible to carry the toning action far enough. A strong print was, however, wanted.

### PHOTOGRAPHIC CLUB.

AUGUST 16.—Mr. H. Snowden Ward in the chair.

Mr. Wallis showed prints from negatives taken during his recent holiday upon what he concluded were stale plates, which showed great numbers of mottled marks and also halation round objects.

The subject for discussion for the evening,

#### THE PERMANENCY OF THE BROMIDE PROCESS,

was gone into at great length.

Mr. BRIDGE was of opinion that, with ordinary care, the process was quite permanent. He had, in the course of his business, made and developed large numbers of prints, and even in those instances where time was important, and he had only been able to give a very short and rapid washing, often, after lapse of long periods, he had found them without deterioration. Too many photographers were in the habit of trying every and any kind of paper, instead of sticking to one and completely mastering it; moreover, most of them were entirely unaware that the latitude in working with ferrous oxalate was as great as any could desire.

Mr. J. BROWN thought that many gave up ferrous-oxalate development because of their many doubtful results, due to not thoroughly clearing their prints in the acid bath, and consequently took to using the new developer, which left nothing behind likely to attack the silver image.

Mr. MACKIE considered that the ability to obtain good results by the new developers, and at the same time to get rid of one process, and that most calculated to introduce doubt, was most important.

Mr. WALTER D. WELFORD was also of opinion that bromide prints, developed in the usual way with any developer, were decidedly permanent, but he could not say the same of toned, i.e., "boiled," prints, which he considered not only uncontrollable in toning action, but in no sense permanent; in fact, he had experienced decided deterioration in two months.

Mr. J. BROWN quite disagreed with Mr. Welford as to the "boiled" prints not being permanent. He had made many such, and, so far as he understood the process, the resulting picture consisted of silver sulphide, and stood tests well, and it was in his hands quite permanent. It was, though, useless to expect good results with new hypo-alum solution; the older the better. He had also tried the various substitution toning processes successfully, and, working them solely for his own amusement—perhaps, owing to his taking every care—they had so far proved permanent; they were, however, for the most part, protected from the air.

Mr. BRIDGE thought that the application of heat evenly had much to do with ease and evenness of toning, and suggested a double dish as likely to produce that result.

Mr. G. A. BROWNE said he had toned prints and lantern slides with uranium, and found them permanent, but thought it most essential that the toning should be full.

Mr. J. BROWN did not consider uranium toning otherwise than doubtful, perfect washing and absolute evenness of action being so essential.

Mr. H. P. SMITH asked if one portion of the deterioration was not traceable to the paper used, particularly that used for negative paper; for, apart from the friable nature not allowing large sizes to be handled, there seemed to be great variation of quality and condition, and he mentioned some qualities of papers as not being liable to this defect.

### FORTHCOMING EXHIBITIONS.

1899.

- Sept. 22-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- „ 25-Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.
- „ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

### Correspondence.

\*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE CAMERA OBSCURA AND THE CAMERA CLUB EXHIBITION.

To the Editors.

GENTLEMEN,—Permit me to thank you for drawing my attention to some remarks, which I might otherwise not have noticed, appearing in the *Journal of the Camera Club*, which reflect upon my critique of the Camera Club Exhibition, printed in the first number of the *Camera Obscura*.

The editor of the former journal is quite right in resenting, on behalf of the members of his Club, any unvarnished personal impression which is not all adulation; indeed, he has a good deal of reason to expect either a respectful silence or an unqualified approval for the Exhibition.

These are, however, not sufficient reasons for saddling me with the consequences of the Club's shortcomings in failing to provide visitors with a catalogue of the Exhibition.

When I attended to inspect the collection, about a week after the opening, no catalogue was to be had. Hence those little clerical errors, which have been so skilfully "enlarged" and adroitly "retouched," although, after all, not corrected.

Under these circumstances, it is matter for surprise that much more error did not creep into the report than, to judge by the somewhat obscurely worded paragraph in the *Journal of the Camera Club*, a wrong number and an obvious *lapsus calami* in calling a print (entitled *A Midsummer Day*) *May-time*.

Let me add, that the mistakes were so few is largely due to the kindness and courtesy of Mr. Craigie, who, during great part of my stay at the Exhibition, was unremitting in his endeavours to supply the information for which one usually and preferably consults a catalogue.—I am, yours, &c.,

HECTOR MACLEAN.

#### VALUE OF ENGRAVINGS.

To the Editors.

GENTLEMEN,—Replying to your correspondent, "Colonel," the coloured engravings he refers to are not rare, but they are to be found in various degrees of excellence. Their value depends entirely upon how excellent they are. I am quite sure that Messrs. Sotheby & Co., of 18, Wellington-street, Strand, would be able and willing to say how much they are worth, i.e., how much they would fetch if sold at one of their auction sales.—I am, yours, &c.,

AJAX.

### Answers to Correspondents.

\*\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*\*\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

S. R. Berry, 10, St. Peter's Paved-row, E., Great Yarmouth.—Photograph of dungeons at Tolhuise, Great Yarmouth.

J. W. Cruickshank, Combe Head, Haslemere.—Photograph of portion of south-west corner of San Michele, Lucca, Italy. Photograph of wheel window at San Zeno, Verona, Italy. Photograph of western facade of San Zeno, Verona, Italy. Photograph of western facade of San Michele, Lucca, Italy.

PNEUMATIC.—We believe the originator was either Mr. James Cadett or Mr. B. J. Edwards.

AN AMATEUR.—We are much obliged to you for your letter, but our correspondence columns are not the place for advertisements.

SWAN'S PATENT FOR CARBON TISSUE.—CARBONENSIS asks the date of Swan's patent, and if it is still in force? The patent was taken out early in the year 1864, consequently it expired many years ago.

PRINTS STICKING TO GLASS.—H. JENKINS. The reason why the "enamelled" prints leave some of the collodion on the glass, when they are stripped off, is that the plates were not properly waxed or French chalked. More care in this is the remedy. The collodion is in no way at fault.

LENS QUERY.—T. COLES. Get an ordinary R.R. A wide-angle lens, covering the same size plate, would be more convenient occasionally, but that convenience is more than counterbalanced by its inconveniences for general work. Not the least of these is its much smaller aperture, and consequent slowness.

STAINED NEGATIVES.—A. B. C. The negative arrived smashed to atoms, as well might be expected to be the case with one sent through the post simply protected by carls. So far as we can see by the fragments, the stains are simply due to imperfect fixation. Bromide paper will not do for printing out upon.

BELLOWS STICKING.—T. A. JEWELL complains that the gussets of the bellows of his camera stick together if it has been folded up for some time, and asks for a remedy.—The best thing we can suggest is, rub the bellows well over with French chalk, rubbing it well into the material, and then lightly dusting off the surplus.

MATT VARNISH.—ALF. KNOWLES asks if the "matt varnish, the formula for which is given in the ALMANAC, is applied to the glass while it is cold, or should the plate be heated? Also whether the varnish should be dried off before the fire, like ordinary negative varnish?—The varnish should be applied cold and dried without heat.

COPYRIGHT.—F. J. A. Although you purchased the copyright negatives with the business, you have no copyright in them, unless the copyright in them was separately assigned to you and the assignment duly registered at Stationers' Hall. As it is, the copyright is still vested in the one who took the photograph, and it is he only who can take proceedings for its infringement.

FELLOWSHIP OF THE ROYAL PHOTOGRAPHIC SOCIETY.—AMBITION writes: "Would you kindly inform me what qualifications are required to become a Fellow of the Royal Photographic Society? How is one to go to work to obtain that name?"—Your better plan will be to address the Secretary, Royal Photographic Society, 66, Russell-square, W.C., for particulars.

RE-CEMENTING LENS.—R. DAVIDSON says: "The back lens of my rapid rectilinear is coming uncemented. Can you tell me if I, who have never attempted such a thing, could succeed in repairing it, and, if so, where I could get a suitable Canada balsam cement?"—We should recommend you to send the combination to an optician, preferably to the maker of the lens, who will do the work for a trifling sum. Doubtless the glasses are burnished in the cell, and you might injure them in getting them out or in putting them back. Canada balsam may be obtained from any of the optical and philosophical instrument makers.

REMOVING STAINS FROM FINGER-NAILS.—M. W. says: "Can you oblige me by informing me what I can use to remove a pale brown stain from the nails? I am a printer, toning a considerable batch of P.O.P. prints in the usual sulphocyanide bath daily, and suppose the bath causes the stain."—The stain is caused by the free silver in the washing waters, and it is somewhat difficult of removal. A strong solution of cyanide of potassium is sometimes used, but it is dangerous on account of its poisonous nature. A solution of iodine, followed by one of hyposulphite of soda, may also be used. The stain, if not very deep, may be removed mechanically with fine pumice powder moistened with water.

\*\*\* We are unavoidably compelled to hold over a large number of answers to correspondents and other communications. All arrears shall be overtaken next week.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The

formulae will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

It is so seldom that we read a commendatory note on professional portrait photography in the great London daily papers that the following criticism in the London *Daily Chronicle* will, doubtless, prove of interest to many of our readers. “The latest photograph of the Queen,” says our contemporary, “is one that all loyal subjects will like to possess, and the first remark upon it must be that Her Majesty does not look her great age. Not long ago the *Spectator* told us that the secret of the Queen's strength as a ruler was to be found in her ‘equable temperament,’ and, looking at the present photograph, one cannot help agreeing in this verdict. Dressed quietly in black, and with a fan lightly resting in her hands, her Majesty's expression is calm, radiant, benignant. Another equally interesting photograph shows the four generations. The Queen, who wears a hat with large white feathers, is seated, and her left arm encircles little Prince Edward, who is in a sailor suit, while on her Majesty's left and right stand the

Prince of Wales and the Duke of York. The photographs were taken at Osborne exactly four weeks ago by Messrs. Chancellor, of Dublin. We have seldom seen examples of the photographic art more charming than these."

\* \* \*

THE Assistant Secretary of the Royal Photographic Society writes us: "May I ask you to be kind enough to remind your readers that all entries for the Forty-fourth Annual Exhibition, to be held at the Gallery of the Royal Society of Painters in Water Colours from September 25 to November 11, close on Wednesday, September 6, at 9 p.m. Exhibits in packing-cases must be delivered at 66, Russell-square on or before September 5."

\* \* \*

IN connexion with the foregoing letter it is of historical interest to note that the next Exhibition of the Royal Photographic Society, which opens a little more than three weeks hence is, in all human probability, the last that will be held in the Galleries at Pall Mall East. Next year the Society will have possession of the New Gallery, Regent-street, for the purpose of its annual display, and the present intention is to make that display not only much larger than it is now, but also considerably more comprehensive. To every branch of photography it is anticipated that the Society, with the space then at its disposal, which it does not now possess, will be able to do an amount of justice which it is not at present in its power to dispense. The pictorial, technical, scientific, manufacturing, and other photographic interests will then, it may be conjectured, be adequately represented for the first time at an annual London Photographic Exhibition.

\* \* \*

CHANCE, or good fortune, has given us the opportunity of seeing a large proportion of the work that is to be sent in next week to the Selecting Committee, and, taking the line by what we have seen, and assuming the majority of the photographs we have examined to be accepted, we have no hesitation in saying that the old Society will show the world a collection of work which will more than justify its original claim to have sprung into existence for the "advancement of photography." In the space of forty-six years the Royal Photographic Society, as it is now called, has, with very few breaks, provided the opportunity for an annual exposition of an ever-advancing, if an ever-changing, manifestation of the wonderful effects and phenomena which it is the province alone of photography to suggest or record, and this month's Exhibition, we are sure, will witness something like an apotheosis of its efforts to attract to its walls, year by year, all that is truly representative of the passing phases of photographic expression.

\* \* \*

OUR own personal experiences of the Photographic Society's Exhibition date back the comparatively short space of twenty years. Brief though that time may be, "many things," as the late Lord Beaconsfield once said, "have happened since then." A wonderful change has come over the appearance of the famous Exhibition. The silver print, with its wide margin and Oxford mount, is rarely seen now in Pall Mall East. In the interim "close-up" framing has come into vogue. Platinum, with its variety of colourific deposit, has sternly challenged gelatine-pigment printing for pride of place. Bromide, toned and un-

toned; collodio-chloride; gelatino-chloride; the short-lived Artigue and gum-bichromate processes, all these and others have been illustrated in the annual Exhibitions at Pall Mall. "Times change and we with them," and so it may be truly said of photographic fashions. What pleases us to-day fails to attract our favourable notice to-morrow. We well recollect one Exhibition which, as if in protest against the previous predominance of albumen prints, was simply a manifestation of bromide and platinum blacks all through. We should not be surprised if this year a similar phenomenon were not witnessed, viz., a revival of rich blacks and the relegation to disfavour of warm tones and muddy browns.

\* \* \*

THIS year's Exhibition will be notable in another respect. For the first time special pains have been taken to choose a large and representative Committee of Selection, the one half of which was deputed to act in the interests of pictorial exhibitors, the other in those of contributors to the Technical Section. This joint committee—or two committees—were given full powers of selection. They are independent of the Judges; their selecting work is to be done before the Judges appear on the scene. In appointing these committees it was apparent to those familiar with the matter that there was no doubt of the intention of the Council of the R.P.S. to dissociate entirely the office of selection from that of judging. In view of this fact, recent complaints that the Judges are denied the opportunity of selecting the photographs upon which they are to be called upon to adjudicate are shown to be futile and absurd. It requires very little effort to show up the unreasonableness of a Judge's claim to select as well as to judge an exhibition. A few years ago a gentleman connected with the Photographic Salon told us that in his opinion not more than two or three at most of the exhibits at a Pall Mall Exhibition were "worthy" of being shown at the Salon! It is this impertinence of idea which underlies the demand for turning the R.P.S. Judges into a committee of selection, and we hope the Society's executive will not give the smallest encouragement to such pretensions.

\* \* \*

SOME idea of the hold which stereoscopic photography is obtaining upon the general public is afforded by the fact that last month Messrs. Underwood & Underwood, the largest producers of stereoscopic photographs in the world, made a sale of upwards of 6,000,000 paper slides, the greatest monthly output the firm has yet reached. Messrs. Underwood's plan of working is to form sets of slides illustrative of different countries, and these are sent out in cabinet form, accompanied by suitable stereoscopes and descriptive notes. They anticipate that their operators will be taking negatives in India, Australia, Africa, and elsewhere for the next four years continuously. It is the endeavour of the firm to secure the recognition of stereoscopic photographs as a valuable educational agency by the American scholastic authorities, and to this end they propose putting on the market a multiple stereoscope which will allow of the examination of binocular photographs by several persons simultaneously. The progress in popularity of stereoscopic photographs among the general public will, no doubt, have the effect of stimulating amateur photographers to take up this branch of work.

\* \* \*

WRITING on the subject of colour photography in our ALMANAC for 1899, we made a suggestion that somebody with

the requisite knowledge and ability should prepare a book fully detailing all that has been attempted or achieved in the production of photographs in colour. Such a book, we remarked, would be of immense value, not only for reference but also to those disposed to make experiments in colour work. We are pleased to learn that our idea is likely to receive at least partial realisation. Mr. E. Sanger Shepherd, than whom perhaps there is no higher authority in England on the subject of three-colour photography, informs us that he has in preparation a volume dealing exhaustively with the subject from three standpoints: the historical, the theoretical, and the practical. Mr. Shepherd has for years devoted himself to a close study of many branches of colour photography, and the unequalled knowledge he has thus acquired should make his work on the subject he has in hand of the very highest value.

\* \* \*

WITHOUT comment or details of any kind, our contemporary, the *Photo Beacon*, prints in its August number a half-tone reproduction from a negative made with the Panoramic Kodak. To the best of our recollection, this is the first example we have seen of the new kind of panoramic photography. The picture, whether reduced or not we cannot say, measures seven inches by two inches, and obviously includes a considerable angle of view. For very many subjects panoramic photography is peculiarly adapted, and we have no doubt that, when the Panoramic Kodak reaches the English market, the nature and dimensions of the picture it gives will make this kind of photography popular with a great many.

\* \* \*

DURING his recent visit to London we had the opportunity of conversing at length with our *confrère*, Mr. F. Dundas Todd, editor of the Chicago *Photo Beacon*, on the condition of matters photographic in the United States. Mr. Todd's future plans include the publication of many elementary text-books on photography, for which he tells us there is a great demand amongst American amateurs. This class of photographer likes his subject presented to him in the tersest language, and to be told how to work in the simplest and most direct manner. English text-books are written to suit a different class, with whom elaboration of language and theoretical and practical ideas are taken as a matter of course. It is perhaps for this reason that English books on photography have not, as a rule, the greatest vogue in the States.

\* \* \*

MR. TODD, who has been absent from Britain seven years, confessed to us that, judging by what he has seen during the last two or three months, the condition of British professional photography compares unfavourably with that of the American. The American professional is smart and alert in his business methods; he is quick to seize and introduce novelties to his sitters, and his relations with the latter differ vitally from the relations usually existing between the British photographer and his client. The better class of American professional man is not afraid to assert his independence by insisting that he knows best what suits a sitter, in the way of pose, lighting, size of picture, and so forth. In fact, he takes up a professional standpoint instead of a commercial one, that is to say, the choice of style or treatment rests with him, and not with the sitter. We have heard one of our foremost British photographers say that the great thing lacking in his *confrères* is

this very independence, which Mr. Dundas Todd describes to us as animating some of the most successful professionals in the United States.

\* \* \*

WE have received from Messrs. Kodak, Limited, a copy of the prospectus of the General Aristo Company, which has just been brought out in the United States. The capital is five million dollars, and the shares offered for public subscription were subscribed, we are informed, 'three times over. Mr. George Eastman is President of the Company, which has been formed to purchase the photographic printing paper businesses of the Eastman Kodak Co., the American Aristotype Co., the Nepera Chemical Co., the New Jersey Aristotype Co., the Photo Materials Co., and Kirkland's Lithium paper. By this combination the control of the manufacture of about 90 per cent. of American photographic printing paper has been centralised.

\* \* \*

IN our LANTERN SUPPLEMENT this month we print from the *Philosophical Magazine* for August an abstract of a paper by Professor R. W. Wood on "The Photography of Sound Waves." Two plates of collotype pictures of sound waves are given in the *Philosophical Magazine*, to which we must refer the reader for the explanatory parts of Professor Wood's paper, as we should have experienced considerable difficulty in doing justice to the original illustrations if we reproduced them. It may be mentioned that Professor Wood is the author of the ingenious method of colour photography by means of diffraction gratings, described in these columns some months ago.

#### REDUCTION AND INTENSIFICATION IN PROFESSIONAL WORK.

IN establishments where a large amount of work is turned out no process for any purpose has a chance of success if it involve tedious operations and delay of execution. "It is all very well," recently said a professional to us, "for an amateur whose photography is only a cherished hobby, but for bread-and-butter work we want a good process, and, if possible, a quick one all through." And, as regards the particular operations we are now discussing, it is the aim of the professional to take negatives where they shall not be needed; but the best of men fail at times, and have to invoke the aid of one or the other of these two necessary but distasteful operations.

We have made a number of inquiries on the subject; and, taking intensification first, we may say the general favourite is one or other form of mercury intensifier. Our own experiments lead us to the conclusion that it is the simplest, safest, and easiest, and, with care, absolutely permanent. The plan in use over forty years ago with wet collodion is still in vogue, and cannot be improved upon—a solution of bichloride of mercury, in which the plate is immersed till white all through, followed, after a good washing, by treatment with ammonia, ammonia hydrosulphide, or other similarly acting chemical. It does not seem to matter much which is employed. We all know the usual objection, that the process is not under control; that, if a negative only needs slightly increasing in density, the mercury process will carry it to such excess as to make it almost useless. These objections are entirely futile. There is no process in the whole range of photography in which results are more under control (we, of set purpose in this connexion, ignore all reference to scale of gradations; we merely refer to

bringing the negative to a density sufficient to give a good print). When the intensification is complete, it can be reduced to any extent required by simple immersion in a weak solution of hypo. What more in the shape of control could be required than a process which will give any depth between the original feeble density and a density almost to opacity? We have had in our hands negatives so treated that showed no signs of alteration after a dozen years' storage, but they were all varnished. We have great faith, too, in the Edwards's intensifier, as modified by Mr. Watmough Webster, who keeps a bottle of red iodide of mercury, made by precipitation, and kept stored in a thin paste, no attempt to dry it being made. When required for use, a five per cent. solution of hypo is taken, and, after well shaking the iodide bottle, the red "cream" is slowly dropped into the hypo till no more will dissolve and a small quantity is left undissolved. When this is applied to the negative, it takes density most beautifully. It should be allowed to give a slight excess of depth, and then reduced by immersion for a short time in weak hypo. This has the effect, while reducing the excess of depth, of conferring brilliancy, and it seems to prevent the negative fading in after-years, otherwise the shadows are apt to become yellowed after the lapse of time, and the beautiful colour of the negative generally reduced to an unpleasant yellow or sepia.

For reduction there is no doubt that the universal favourite is the Howard Farmer reducer. A stock solution of twenty per cent. ferricyanide of potassium is kept on the shelves, and, when reduction is needed, it is only necessary to add a drachm of this liquid to two ounces of the ordinary dark-room hypo to obtain a liquid that acts most efficiently. If used very slightly, it confers brilliancy by clearing the shadows, though it must be admitted that, if any considerable reduction is needed, the lighter tones disappear entirely. Its use, therefore, is contra-indicated in the case of negatives which err, if at all, on the side of under-exposure. Here the excellences of the new agent, persulphate of ammonia, become conspicuous: it does not eat away the light tones at the expense of the quality of the plate, and does essentially, whatever the cause may be, act more upon the strong high lights than the slighter deposits of the image. There is no doubt, too, that, until properly understood, stains and spots may be produced under its use. Thus, if a plate so reduced be placed under a rose jet of water, an iridescent spot appears under each little stream of water; but, if after the slightest amount of washing such a plate be put in a ten per cent. solution of sulphite of soda, the iridescence instantly disappears, and it may then be again slightly washed, and finally put in a bath of ten per cent. hypo, or, indeed, the ordinary hypo fixing bath of the dark room not diluted at all. The plate then, after being thoroughly washed, will possess a very high quality if it were originally a good one.

We may say that in the four methods thus briefly described we have all that we need desire for portrait or landscape intensification or reduction.

**Royalty and Photo-Ceramics.**—We last week said that, while the Duchess of York was staying at Longford Hall, she visited the Royal Glass Works at Hatton, and subsequently the establishment of the Photo-decorative Tile Company. Here she sat for her photograph, which is to be reproduced in the form of "photo-models." Photo-ceramic work and photo-sculpture has never "caught on" to any great extent, but for what reason it is a little

difficult to say. When, some years ago, the Princess of Wales ordered a tea service to be decorated with photographs of her own taking, it was surmised by some that an impetus would be given to ceramic photography by the *élite* of society, but it did not to any great extent. Photo-sculpture was introduced in the early sixties by François Willème, and worked commercially in London by the late Mr. Claudet. By this process both busts and bas-reliefs were produced in Parian and plaster and very excellent they were, yet the thing was not a commercial success. During late years several different patents have been taken out for producing bas-reliefs in various plastic materials and metal, but the demand has hitherto been limited, why, as we have said before, it is difficult to surmise.

**"Faked" (?) Photographs.**—On more than one occasion we have alluded to photography in connexion with the famous Dreyfus case in France. Amongst the most amusing evidence, according to the reports that have been brought forward by the prosecution, is that of the expert in handwriting and photographer, Bertillon. It is said that, at the close of last Friday's proceedings, the counsel for the defence, with experts, were occupied in carefully examining the photographs shown in the Court by M. Bertillon, and they have come to the conclusion that they must have been touched up. Of course, the defence will call for the negatives from which the photographs were made, and if they succeed in obtaining them, which in this extraordinary case may be doubtful, the sophistication will be exposed. The sophistication of photographs, whether negatives, prints, or enlargements, that are shown as evidences of handwriting or forgery, is nothing less than forgery itself. But in this famous case forgery has figured so largely that photographic forgery may pass unheeded, though it is doubtful if Me. Labori, the unfortunate prisoner's counsel, will allow it to do so—that is if he can help it.

**Another New Telescope for Photographic Purposes.**—The New York correspondent of the *Standard*, writing one day last week, gives an account of the new telescope now being constructed at the Harvard University for photographing the new planet, Eros. He says the designed focal length is 162 feet, while the aperture may not exceed a foot by more than one or two inches. It is intended to mount the instrument permanently in a horizontal position, and to observe or photograph the image by a mirror, the earth's motion being compensated for by a clockwork arrangement. This novel instrument, designed, we believe, by Professor Pickering, will be practically a horizontal photo-heliograph, and will give images of the moon exceeding a foot in diameter, even without enlargement, and it is expected that it will surpass the best instrument yet made. A well-defined photograph of the moon, taken direct without enlargement, over twelve inches in diameter, will be both interesting and valuable. We congratulate our American cousins on their enterprise in astronomical matters and also on the possession of the finest large telescopes in the world.

**The Guérin "Blockade" and Photography.**—Most people have read with some degree of amusement about "Fort Chabrol" in Paris, in which Mr. Guérin and a few of his followers have installed themselves, its attempted siege and blockade. Doubtless, many photographs, and also cinematographs, have been taken from the surrounding houses of the scene and the tumults in front of the "fort"; all these are, of course, interesting. We now read that Mr. Guérin spends some portion of his time in smoking cigarettes and taking snap-shots of the gendarmes, police, and firemen who are blockading his fort. Now, for this kind of work he is at a great advantage over all outsiders, for from nowhere can they be seen to such advantage as from his fort. A collection of these photographs, if published, would, doubtless, command a considerable sale throughout Europe and America, as illustrating how one man and a dozen or so of his followers keep the gendarmerie, police, and firemen of Paris at bay for several weeks by simply threatening to shoot.

**Engravings and their Value.**—We have frequently chronicled the high prices that engravings sometimes realise at auction sales. A fortnight back a correspondent wrote, asking the probable value of a couple of engravings he possessed—reproductions of Morland's paintings. We are quite familiar with these engravings, and they are of various degrees of merit as prints, and their commercial value is in accordance. When the high price sometimes quoted is given, it is by connoisseurs for exceptionally fine prints. One print may fetch, say, fifty pounds, while others from the same plate may only realise a few shillings, so much depends upon the state of the plate when the impression was taken. When talking to an old copper-plate printer on this subject some time ago, he told us, as an expert, that he could detect a difference in the quality after twenty impressions had been taken from a copper plate, and a very marked difference after forty or fifty impressions had been pulled. This will fully account for the different values of prints from the same plate. With steel plates the difference between so small a number of impressions is not so manifest as with copper plates—that is, the copper plates of forty or fifty years ago, before "steel facing" was introduced.

STEEL facing, it may be mentioned to the uninitiated, consists in depositing on the copper surface, by electrotyping, a thin layer of iron in an exceedingly hard state, hence the term "steel facing." That is always done with photogravure plates, which are of copper. In this way the copper plate becomes as durable as if it were of steel itself, practically more so; and for this reason, when the iron surface shows signs of wear, it can be cleaned off by simply dissolving it off with dilute sulphuric acid, and then depositing a fresh coating of the iron. By this means the plate becomes practically everlasting; and, if care be taken not to use the plate after it begins to show signs of wear, and before refacing, there will be no material difference between the two-thousandth impression and the first proof. It might be thought that plates with delicate detail, such as photogravure plates, would have their delicacy impaired by the film of iron, but that is not so in actual practice. Theoretically it is, but that is met by the fact that the steel surface has, as it were, a greater ink-holding property than the bare copper would have. In the old days of copper-plate engraving—line and mezzotint—steel facing was unknown; hence the great difference between the first proofs and later impressions, and the difference in their value in the eyes of connoisseurs.

#### ON THINGS IN GENERAL.

I HAVE always understood that the editorial and the advertising departments were distinct and different institutions in connexion with journalistic matters generally, though, I think, if the truth were known, there would be found a mysterious bond existing, a bond that links but which yet is not without its moments of chafing, when, indeed, the office chair is not a bed of roses. Otherwise, how is that we see in the society papers, for example, that when some special article, some specific for personal use, or say editorial discomfort, receives flattering notice, we can generally find in the non-literary columns a paying "ad." upon the subject? I don't, of course, for a moment think a high-toned paper like the "BRITISH," for example, could be influenced in such a direction—far from it—a glance at a few weekly issues will show that no such base influence exists therein; and, indeed, the fact that led to this train of thought had a direct contrary tendency. I happen to have an English-made quarter-plate camera—quite recently introduced, it is true—up to date in every way, leather-covered swing back, compact, portable, lens with T. & I. shutter—in fact, a model camera; yet, when I opened my JOURNAL one morning, after fondly putting away my new toy, I noticed our genial "Cosmos" lamenting that no English manufacturer could be found to put on the market a camera like those excellent ones sent out in

such numbers from the various Rochester manufactories. Yet, and here I come to my point, the particular camera I refer to was at the time advertised, and had been advertised, in the very columns of this JOURNAL. It is evident that, however up to date the maker was in producing cameras, he was lamentably deficient in "business go," or he would have shouldered—or, rather, pocketed—his camera and invaded the editorial quarters at the earliest date. If it were not contrary to journalistic ethics, I would name the camera. My readers may find it for themselves in the advertising columns. Apart from this question, it is positively marvellous to note the ingenuity displayed in the production of the modern quarter or third-plate camera. Within a space of less than six inches square or about two inches thick to find concealed a first-class camera with swing back, rack-work focuser, leather bellows, lens, high-class shutter, &c., would appear almost impossible were it not to be seen in every dealer's shop in the country.

Speaking of dealers calls to mind the painful letter from "A Would-be Dealer" which appeared a week or two ago. A photographer, deciding upon starting a store for photographic materials, altered his premises, and ordered his plates. When too late, he found that he could not buy his plates wholesale because a certain society had determined that photographers, though they were *bona-fide* dealers, were not to be supplied at wholesale price unless they had special permission, and such permission was withheld in the present case. The Editors of this paper have time after time girded, and properly so, at the photographer for permitting the chemist to usurp his proper functions in supplying amateurs with materials. He recked not of the "Manufacturers' Association." Lest others may be inclined to follow that advice, and be disappointed like the correspondent above mentioned, I should like all photographers to know that most of the plate and paper-makers have combined to fix terms—a very proper thing, it may be observed *en passant*; but they publish no rules, and they have hitherto only been heard of incidentally, and do not inform inquirers what sales or purchases must be made to entitle the inquirer to be put on dealers' terms. A recent circular of one of the plate-makers as sent out to wholesale dealers, *i.e.*, those who supply the retailers, says: "No manufacturer shall allow more than the above terms [*i.e.*, a *maximum* of ten per cent.] to any photographer, whether he is also a dealer or not, without the consent of the manufacturers." Well, no one can grumble at this—the manufacturers have a perfect right to sell on what terms they like; but their application of these rules is liable to have an illiberal construction put upon it. Thus, any little chemist or stationer has had no difficulty whatever in expending a few sovereigns in a stock of plates and buying wholesale; but, when a photographer does a sale business large enough to bring in an income more than that of an average operator, he is refused permission to buy, except at such prices as will leave no profit whatever. I will conclude this part of my letter by a little matter of history. The coal-tar dye industry was originally a purely British one. It was confined to a very few makers, and some idea of its magnitude may be formed when I say that out of the manufacture of magenta alone it was commonly understood one firm netted a quarter of a million of money! Things went on merrily. The manufacturers declined to share profits where a legitimate expectation of sharing might be expected. Moral: The trade has left this country. For one ton of such dyes made here, far more than twenty are made abroad. Again, a quarter of a century ago British albumenised paper was the best in the world; the foreign make was a striking abomination. Nowadays the foreign commands the market. History repeats itself. There was no dye like the British. There is no plate like the British. What will be the case in a few years' time?

*Apropos* of this aspect of matters, remarks have been made upon the fact of so few amateurs taking up that beautiful process, carbon. Here the very question first discussed creeps in again. It is true there are very few professional photographers even who do carbon work on their own premises, but wherever it is done, surely there, of all places in the world, should the Editors' advice be taken and the professional photographer give lessons and supply material. But he is precluded from doing so by the fact that the carbon-material manufacturers

of the country do not encourage the amateur to get his materials through middlemen, on account, one must suppose, of the liability of the process to incur disfavour if stale materials were to be sold.

Respecting carbon work, it is well known that the leading objection to its use for portraiture is the fact that a direct carbon print gives a reversed image, and that to get it non-reversed involves the transfer of the print to another piece of paper. This is an operation liable to failures, but can easily be mastered with care and practice; while for enlargements, of course, it is only necessary to take a reversed negative, which gives a non-reversed print. It is not known to every one, but all practical photographers who have had experience in enlarging are aware, that if a portrait is reversed it is invariably a dead failure. This is singular, but true. Of course, the explanation is that faces are not symmetrical, and the want of symmetry is at once seen when the features are presented in an unusual way, as is the case when they are reversed. In the old wet-collodion positive days people were not so particular; a portrait then was a curiosity, and more interest was shown in the marvellous truth with which a piece of lace was reproduced than in the mere features. But, even in those days, I call to mind one photographer—a Liverpool artist, who did some of the best work in the country—who invariably mounted his portraits with the collodion side down, and so had them non-reversed.

There is a reference to collodion in the Correspondents' column, p. 528, where an inquirer wants to get ether as cheap as they can buy it on the Continent. The Editors rightly draw attention to the fact that, if it could be bought cheap there, it would become dear if it were brought here because of the duty that the Excise would enforce. But "Collodion" may be interested to know that he can buy ether made from methylated spirit for one-fourth the price of that from pure spirit. For such purposes as enamelling the methylated ether is every bit as good as the other, but for wet collodion its use is to be deprecated. All old-collodion workers are familiar with the penetrating, eye-smarting effect of coating a plate with old collodion. No such effect was produced when collodion was first sold at about a shilling or eightpence an ounce, but when the price came down to ten shillings a pint methylated solvents became the rule, and operators' eyes suffered in consequence. The effect was caused by the action of the iodine (liberated from the iodiser when the ether became "ozonised") acting on the wood naphtha, when the acrid compound was quickly produced.

In the same column I note an inquirer asking about cheap lenses and the Editors giving some sapient advice. I should like to add to the list of advantages that accrue from purchasing a good lens by a well-known maker. If occasion arise when it is desired to sell or exchange a lens, it will usually be found that a lens by an unknown maker will fetch very little indeed, while one from a maker of repute can always be sold with a small margin of loss only, and this is a very important point to consider when purchasing.

I read with much interest Mr. Pike's remarks upon cheap advice and cheap cameras, and I agree heartily with most of them. Where I disagree with him is in the comparison he makes between, say, a guinea and a ninety-shilling hand camera. Now, I have handled and examined some scores—I may say hundreds of hand cameras, and my opinion generally is that in no class of camera work made do you get more value for your money than in the various makes of hand cameras. With regard to requiring, when four guineas is paid, that the lens should be by a recognised maker of repute, it should be noted that, if we examine the lists of, say, Ross or Dallmeyer, a 5 or 5½-inch lens, that being the usual hand-camera focus, will almost reach that sum of itself.

I was much struck in reading the account of American dry-plate manufacturers by Mr. William F. Miller that the light employed is a deep ruby, and never a combination of orange and ruby. Now, if any one will put a plate under a piece of ruby glass and one of double-flashed orange, and allow the light to pass through, he will find on development that the ruby, which to the eye is much darker than the orange, will give a much-fogged plate after an exposure that will leave that under the orange plate intact. Surely there is something here requiring explanation.

FREE LANCE.

## THE ORIGIN AND HISTORY OF CERTAIN TRIPLE ANASTIGMATS.\*

DR. RUDOLPH STEINHEIL and Emil von Høegh, of Wilmersdorf, Berlin, in Eder's *Jahrbuch* for 1897, described respectively the origin and history of the orthostigmat† and the triple-lens anastigmat.‡ Dr. Steinheil's paper was largely concerned with the development of the late Adolf Steinheil's researches, and is of very great interest, though perhaps fuller details, especially as regards the mathematical part of his work, might well have been gone into.

After Adolf Steinheil had discovered several constructions in astronomical optics, he set to work in the province of photographic optics, then, especially, a much more difficult one. The first result of his labours in this direction was the "periscope," a double-lens objective consisting of one sort of glass only (fig. 1).§ For this very reason, however, though marred by the non-coincidence of the "visual" and "chemical" foci, in all other respects it fulfilled the conditions of a photographic objective. Thus, by the employment of small apertures, a field of vision of 90° may be obtained; astigmatism in this field up to 30° was nil (see fig. 2). His attempt to make the periscope achromatic led Steinheil to the construction of the "aplanat" (fig. 3). This was free from chemical focus, and gave great sharpness at  $f/18$ , but astigmatism appeared already at the tenth degree of the field of view (see fig. 4). Endeavours to lessen the astigmatism led to the "wide-angle aplanat" (fig. 5). The astigmatism in this did not appear till about the fiftieth degree (see fig. 6), but at the expense of sharpness and flatness of the object. In the course of these researches Steinheil had already discovered that the astigmatism became less in proportion as the exponent of refraction of the crown glass approached that of the flint glass. On this account he worked out the wide-angle aplanat with light and heavy flint instead of with crown and flint. The attempt to produce the positive lens out of a more highly refracting medium forced him at last to give up the symmetrical form of the aplanat, and led him to the unsymmetrical type of "antiplanat." This objective, called the "group-antiplanat," thus evolved, was the first objective which contained an element of correction of astigmatism; nevertheless, it could not be made to act satisfactorily on account of the sorts of glass which were then obtainable. With regard to astigmatic correction the following principle may be laid down: An objective can be astigmatically corrected if it contains between two media a dividing surface which turns its concave side towards the more strongly refracting medium. Similarly, an objective can be spherically corrected if it contains a dividing surface between the two media which has its convex side turned towards the more strongly refracting medium.

From these two principles it may at once be seen that it is impossible to construct, out of only two lenses, an objective from which the chromatic, spherical, and astigmatic errors are simultaneously eliminated, a proposition which has long been known. Neither, of course, can a spherically and astigmatically corrected system be produced by the combination of two such symmetrical double-lens objectives. The attempt must be made to produce such a system by the employment of only four lenses, divided into pairs by a large interval. In this case it will be found necessary that the dividing surface between one pair should turn its concave side to the strongly refracting medium; the surface between the other pair should turn it to the weaker; then one pair will be astigmatically, and the other spherically, corrected. This arrangement occurs in the "group-antiplanat," as may be seen from fig. 7, in which the index of refraction of each lens is written on it. There was, however, still one defect to be found in this construction, the correction of which was quite impossible for A. Steinheil. At that time there were no glasses which, when they were of higher refraction, were not also necessarily of greater dispersion. Consequently the astigmatic correction in one pair of lenses could not be made good enough, because in so doing other errors were entailed in so great a degree that it was impossible for them to be eliminated in the other pair of lenses. Thus, in point of fact, fig. 8 shows but small advance from fig. 7.

As soon as the Glastechnische Laboratorium succeeded in producing a glass of higher refraction with lower dispersion, this difficulty disappeared. Indeed, the anastigmatic objective, patented by the firm of Zeiss, in Jena, is of the same arrangement as the "group-antiplanat," only the flint glass in the first lens of the antiplanat is replaced in the anastigmat by the new glass, and the front and back lenses are exchanged

\* Communicated by Philip E. B. Jourdain. Figures may be found in Eder's *Jahrbuch* for 1897, pp. 173-180, where fig. 31 + x corresponds to fig. x here.

† "Entstehung und Geschichte des Orthostigmat." *Jahrbuch* for 1897, pp. 172-181.

‡ "Ueber dreilinsige Anastigmate." *Ibid.*, pp. 75-80.

(see figs. 7 and 9). It is clear from the above reasons that the introduction of this new glass produces a far better correction of the astigmatism, and also that the Zeiss anastigmat much excels the "group-antiplanat" in anastigmatic flatness of field (see fig. 10). Having become acquainted with this new glass, the idea now occurred to Steinheil to introduce a correction of astigmatism into the anti-planat with the help of this new glass. Naturally the halves of the same must consist of not less than three lenses, since they must be spherically as well as astigmatically corrected, also they must contain at least two dividing surfaces between two media. He discovered two forms of this sort. In one a negative lens is enclosed between a biconvex lens and a positive meniscus (fig. 11), of which one possesses a higher, the other a lower, refractive power than the enclosed negative lens. The second form consists of a positive meniscus, which is enclosed between a biconvex and a biconcave lens (fig. 12), which both possess a higher refractive power than the enclosed meniscus.

The mathematical calculation of these two forms was of long duration—many months, in fact—as Rudolph Steinheil was then being instructed by his father by this very work, "and a free hand was given to him in order that he might gain experience by making blunders." At last a specimen of aperture  $f$ -12 was made, and on March 25, 1893, a patent was applied for with the following claims:—

An objective which consists of symmetrical or similar (differing only in scale) halves, each half formed of three cemented lenses, of which (1) the first is biconvex, and consists of a kind of glass which possesses the highest refractive power of the three employed; (2) the second lens is biconcave, and is made of the most dispersive of the three sorts of glass; (3) the third lens is a positive meniscus, and is made out of glass which possesses less power, both of refraction and dispersion, than the second lens. The lenses in the other half are united in reversed order.

Thus, a patent was applied for for only one of the two discovered forms of the antiplanat, but in this he was forestalled by Goerz, of Berlin. With regard to the published announcement, Steinheil, in his paper, stated: "This announcement of the patent (on May 5, 1893) was on the same principle as the previous one, though, indeed, in the first announcement, that discovery of Steinheil's, for which the patent had principally been sought, did not occur. So that, only after this thing had been mentioned by C. A. Steinheil, did the applicant so formulate the definition that it did not comprise something else which had long been known. In the new form of Goerz's patent the conditions were almost exactly the same as those stated above. Some differences were, indeed, to be found, which at first gave some hope that a patent would be conferred on both inventions. In any other country this would have been, and indeed has been, the case."

But Steinheil's patent was definitely refused in 1895, and he somewhat naively remarked that "the next thing to be done under these unfortunate circumstances was to unite with the more lucky applicant, Goerz." But an attempt to do this collapsed.

In November 1893 the second constructive form—a positive meniscus enclosed between a biconvex and biconcave lens—was announced as a supplement to the application for a patent on March 25, 1893. The Office of Patents declared this to be of a nature varying from that of the first, and that consequently it could not be treated as a supplement to it. It had, therefore, to be handed in as a separate application. When it was finally brought out, the firm of Goerz laid claim to it also, and succeeded by continuous protestations in causing the patent to be granted only in July 1896 (No. 88,505).

Meanwhile the objective of the first form, under the name of "Orthostigmat, Type I," in two series, C of  $f$ -7 and D of  $f$ -10, was made by Steinheil in Paris, where a patent had been granted to them. (Fig. 13 shows to what degree astigmatism is eliminated in Series C.) In Germany these objectives may not be produced or sold, since the protestation of the Steinheil firm in the summer of 1895 against the infringement of their right of precedence has not yet (1897) been attended to.

The Patent, No. 88,505, appeared as Type ii.  $f$ -68 (correction shown in fig. 14).

Finally, Dr. Steinheil again, rather naively, remarked that unfortunately Adolf Steinheil died three years before even this one objective was allowed to appear "with the knowledge that honest labour does not always succeed in German territory when moral certainty of justice and the literal interpretation of legal paragraphs stand opposed to each other."

[Note by Mr. Jourdain.—It was quite impossible not to believe in the complete independence of Steinheil's work, but it is even still more so now that Dr. Steinheil has so frankly given the historical development of a very remarkable discovery in the theory of optical instruments. I regard this paper as important, not only on account of its literary interest as

showing the amount of credit due to an eminent worker in optics, but also, and in a far greater degree, as giving an outline sketch of the means employed for attacking a very important scientific problem. From this point of view it is of the highest educational value, an initiation into the methods of a very capable man—a lesson which cannot fail to bear fruit if studied, and which cannot be found in "text-books." It is much to be wished that English opticians would, with this object in view, sketch their own mental processes with greater mathematical details than Dr. Steinheil has done].

DOROTHEA PEVERIL TURNBULL.

(To be continued.)

## ESSENTIALS IN THE SUCCESSFUL DUPLICATION OF NEGATIVES.

TWENTY years ago the systematic reproduction of negatives was probably unknown; sporadic cases occurred which could not be set aside, but the results were predestined to mediocrity because of the traditions that hung over any negative bearing the impress of duplication. To-day prints from reproduced negatives gleam at us from every shop window, and glance down upon us from even exhibition walls, yet the wisest among us hesitates in pronouncing upon the primigeniousness or otherwise of the negatives. So imperative became the need for reproduced negatives bearing some measure of primal excellence, that constant effort and improved methods broke through the tradition that any reproduced negative must of necessity stand apologetically as a reproduced negative, and beg the world to lay aside its criticism where it was concerned. And yet at the present time there are many to whom the duplication of a negative is little less than an ordeal where it should be a matter of course, and the result a whited sepulchre where it should challenge comparison with the original. It is for the help of these individuals, who in all probability need but a few hints of essentials to set them on the right road, that these lines are written.

The first essential in negative reproduction is a suitable transparency, and, taking all things into consideration, it is difficult to beat carbon for this purpose, the tissue specially prepared for transparencies being implied. The transparency must be fully, but not over, printed, and should be clear and crisp in appearance, with bare glass in the highest lights only. Too much attention cannot be paid to securing the best result that the negative will give, and time and trouble expended in procuring a high-class transparency are well repaid when the time comes for making the reproduced negative. Above all, aim at securing a "clean" result, as defects in any form assert themselves most unpleasantly in the reproduced negative, especially if it is an enlarged one. It is a good plan to get a transparency at the outset from any negative that is likely to be of more than passing interest, for, by procuring the transparency before the negative is put into the printer's hands, one ensures freedom from that legacy of spots and blemishes that a much-printed negative is so ready to bequeath. Give the transparency, when obtained, a coating of good enamel collodion, well filtered, and to which some germicide has been added, store in a dry place; then, when the original negative comes to grief or requires duplication, you will reap the reward of a thrifty and provident action.

But suppose the negative you desire to reproduce is rather over-exposed and flat, and in all probability thin as well. In such a case carbon is probably not the best medium for the transparency, as it is difficult to get the vigour and gradation from such a negative that are desirable, and intensified carbons are rather to be avoided in reproduction work. When such a negative has to be worked from, a transparency on a slow dry plate gives by far the best result, as exposure and development can be made to obviate in a great measure the defects of the original. In fact, where such an original exists, it is quite easy to supersede it by making a reproduction with at least fifty per cent. more printing quality. Do not make the dry-plate transparency dense, that is a fatal error; the shadows must be perfectly transparent, not having the heavy "blocked" appearance so easily obtained when using dry plates for transparencies.

Where necessary, print clouds in the transparency; this saves a vast amount of labour in double printing if the landscapes require clouds inserting, and in such processes as platinum and carbon printing, where successfully masking the landscape portion is not always easy, the gain is obvious. The neatest and readiest method of introducing clouds in the reproduced negative is to have a series of carbon cloud transparencies on plates a size larger than the landscape transparency; thus, for whole-plate transparencies clouds on  $12 \times 10$  plates. The

clouds in the 12×10 transparency should be printed well above the meridian of the plate, and carefully vignetted away at the lower edge, so that we have delicate clouds on the top half with almost two-thirds of the plate represented by bare glass. Against this cloud transparency, the landscape transparency, with its sky portion perfectly bare glass, is placed and carefully moved about until the sky portion is occupied by a suitable mass of the carbon clouds, the clear glass portion being against the landscape part of the transparency to be copied. The landscape transparency is then supported on the cloud transparency during copying operations by two strips of strongly gummed paper along either edge. It is perhaps necessary to say that the cloud transparencies should be either varnished or collodionised to prevent abrasion.

Much has been said and written against the use of dry plates for reproduction work, wet plates being extolled in the most extravagant manner. After fifteen years' experience with dry plates for this class of work, I can commend them with the utmost confidence, as giving results in no way inferior to the finest wet-plate reproductions, provided always that care is exercised in selecting a dry plate suitable for such work. It should be slow—i.e., about 40 H. & D.—fine in grain, and not thinly coated. "Process" plates are not suitable for this work, at least those prepared for "line" work are not, although I know of one important firm who very recently were making all their reproductions on these plates; but the results were extremely unsatisfactory, as, in order to avoid black-and-white prints, the negatives were kept thin, with the consequence that the print had a uniform dead tint significant of unskilful reproduction. The exposure should be nicely timed, and the plate will then develop exactly as though it were a landscape negative at first hand, the density, of course, being neither greater nor less than would be given to a primary negative.

Equality of illumination is a point that requires very careful attention, otherwise the reproduced negative will be patchy and of uneven density. An amount of unevenness in the illuminating surface that would easily be overlooked by the eyes would be quite sufficient to mar the evenness of the reproduction. The most reliable source of illumination is a clear space of north sky filtered through ground glass; failing this, satisfactory results may be obtained by using a white reflector behind the transparency, care being taken that nothing in the vicinity casts the least shadow on its surface. Rigidity of apparatus is also a point very apt to escape attention, and, where the exposures require to be of some length, as in large cities during the winter months, much annoyance may be caused through loss of plates by vibration. Finally, in cold winter weather too much attention cannot be paid to keeping the solutions at a constant and suitable temperature; it is impossible to get good, uniform results with the developer varying in temperature, and often as low as 50° F.

GEORGE T. HARRIS.

#### FLORAL PHOTOGRAPHY.

"Nor all flowers serve well for photographs. The beauty of the picture is enhanced by considerable masses of light and shade and by rounded forms giving gradations of shade. A multitude of small blossoms scattered over the plate," says Mr. J. A. Anderson in the *Photographic Times*, "is not likely to prove satisfactory unless the arrangement of stems and foliage gives pleasing lines and masses. With flowers in this connexion may be included other subjects, as wheat heads, oats, some grasses, a branch from a cotton plant with fluffy balls, many weeds, &c.

"Pansies are very effective when properly selected as to colour and its distribution. The brilliant reds and yellows of poppies have not, with the writer, proved effective in the photograph, even with the ortho-plate and yellow screen.

"The drooping of flowers during exposure often causes failure. To obviate this, some successful workers lay the flowers on a glass plate, with the background below, the camera being so suspended as to point downward. With this plan water cannot well be used for keeping flowers fresh, and the petals even in this position are still liable to droop.

"A serious objection lies in the reflections from the glass. These may be avoided by using ground glass or celluloid with a dull surface, but this shows shadow of the subject, which also is not a desirable feature. The shadow may be removed by reflectors, but this also removes the shadows in the flowers and makes a flat picture.

"Some good apparatus has been devised for supporting the camera pointing downward, and the glass upon which the object photographed lies. The best to which the writer's attention has been directed is well adapted to the purpose, giving all necessary adjustments. Its weight is about fourteen pounds. The writer has constructed an arrangement weighing as many ounces, in which the camera is supported by the tripod legs. The tripod head, with one leg, is attached to the camera in the usual way, the other legs, connected with suitable pins, in a light strip,

attached by a simple method to the top of the camera, which, in the changed position, is the front.

"The adjustments are readily made by the legs. A celluloid sheet, with dull surface, lies on a light frame, suspended from the legs by strings, and kept from swinging by a chair set against it. This whole method, however, is objectionable for the reasons before indicated, and the vertical position of the subject seems to be the best.

"It certainly admits of more natural and artistic arrangement than can be made with the other plan and better opportunity for correct lighting of the subject and the background. If flowers are photographed immediately upon being gathered, they will often retain the desired position during a considerable exposure. It is well to know, however, that after cut flowers have been in water for some hours the drooping ceases for a time, and the exposure may then be made with little risk of movement.

"The background is an important feature. Some recommend black for general use. This does very well for some subjects, but for most the writer has found a grey the most pleasing. Grey packing board, drawing paper, or wall paper, all do well. Where specks or markings exist on the surface, they may, if not too large, be obliterated by placing the background far enough behind the subject to throw them entirely out of focus. The writer's best results have been with a yellowish-grey felt wall paper, two or three feet behind the subject, and shaded from light below to medium dark above by adjusting the window curtains.

"In selecting the subjects to be photographed the first thought is apt to be of a bouquet or mass of flowers placed in an attractive vase. This, no doubt, is often pleasing, but more artistic results may be had by discarding the vase and showing only the flowers with stems and foliage. Again, a few flowers, and sometimes a single one, may prove more effective than a group of many. A mass of lilies of the valley is always beautiful, but a spray or two of the flower, with a leaf, may make a preferable picture. A single rose may be better than a large bunch. With pansies, daffodils, and other small flowers, several blossoms may well be used, but even with these the number should be limited, both on account of better general effect and the larger size possible for each blossom. Foliage should be introduced when practicable. This is often as effective as the flower.

"The general arrangement of the subject should be such that it shall appear suitably on the plate, covering it artistically in graceful lines, and not too close to the edges for effective margins, although a spray or leaf may be cut by the side of the plate if the general arrangement renders it desirable and the proper balance is preserved. This is often better than having it terminate very close to the edge. In this part of the subject, however, experience and observation must guide, with such taste as the operator can apply.

"The flowers, if the support is not to appear, may be placed in bottles, or held up by clips, or even suspended by the stems from some extemporised support. Dandelion seed heads, that refuse to stay as placed, were strengthened by flexible wires run up the stems. Such wire may be placed behind stems or blossoms to keep them in position. A cork or bunch of cotton in the mouth of a supporting bottle, or a clip, properly placed, may serve a like purpose.

"It is well to get the parts as nearly as may be into one plane. This cannot be done accurately, nor is this desirable, but an approach to it admits of focussing without excessive stopping down and consequent lengthening of the exposure. Also, if the difference in distances from the lens is considerable, the relative proportions as to size are not preserved.

"Sharp focus everywhere may not always be best. A receding spray or leaf a little out of focus may be a good feature, but one projecting unduly toward the camera will appear larger than it should, and its lack of sharpness will mar the general effect.

"True colour values cannot be obtained without the use of orthochromatic plates.

"The writer has understood that success had been attained with plain plates and very long exposures, reducing the light where necessary to obtain this. He has met with no success in this direction. Where yellows and deep reds occur, the yellow screens seem to be needed in addition to the orthochromatic plate.

"This, however, prolongs the exposure to four or five times the length needed without it, and it should not be used when it can be avoided.

"A slow plate gives best results. Acting upon the advice of a gentleman of much experience in this line, the writer has found Cramer's slow isochromatic plate entirely satisfactory. As to size of plate, this must depend a good deal upon what money one wishes to put into his work. The writer began on very small plates, and now uses 5×7. A large plate gives opportunity for better display of the subject, but whether this compensates for the additional cost, &c., each must determine for himself.

"The length of exposure depends so much upon variable conditions that it can only be found by experience. Careful notes made of the light, aperture, plate, subject, and other conditions, will aid in determining the time, which, with the writer, has varied from three to thirty or more minutes.

"Placing the camera with reference to the subject will not be difficult when one has become accustomed to working. To the beginner the following simple rule may be useful: Add together the size in one direction of the part of the subject to appear on the plate, and the corre-

sponding size desired for the image. Multiply the sum by the focal distance of the lens. Divide the result by the size of the object for the distance of the ground glass from the optical centre of the lens, and by the size of the image for the distance of the object from the same centre. When the lens has been placed by this formula, a little fine focussing is all that is needed.

"It is well to use a short-focus lens, especially if working anywhere near the full size of the object. Full size requires extension of the camera to twice the focal distance of the lens, which most cameras will not admit of with lens of long focus. It is to be noted, too, that double the distance requires four times the length of exposure required for the same aperture at the equivalent focal distance.

"A northerly light is best. If this is not convenient, and an exposure has to be taken with strong light, the light should be diffused by tissue or other means.

"As for printing, the best effects are found in platinum.

"Mounting must depend somewhat upon the use to be made of the print. A pure white card framed with a mat is always pleasing. The shaded 'Rembrandt' mount, black or grey is fine, especially if the print is made with a narrow white band around it."

## NOTES ON PEROXIDE OF HYDROGEN.

[Journal of the Photographic Society of Philadelphia.]

It is well known that certain bodies can, in the dark, act on the photographic plate. This action has been attributed to various causes. It is the purpose of this paper to show that it is probably due to the generation of hydrogen peroxide. It must be noted that these bodies act only in the presence of moisture. The plate always contains moisture, and would probably be inactive if quite dry. The change in the plate is rendered visible by the ordinary process of development. Quick plates must be used, as many pictures are formed only after very long exposure.

All of the results produced by metals and organic bodies on the plate can be produced by  $H_2O_2$ . The commercial three per cent. aqueous solution works as well as pure specimens of the same strength. To test the action of any liquid on a plate, we use a small crystallising dish, resting the plate on top of it. The amount of liquid determines the distance between the plate and solution. If we use pure water, we get no image. A trace of peroxide added will produce darkening of the plate. One part of peroxide in 1,000,000 parts of water, exposed eighteen hours, will produce a faint image.

Blotting-paper, by itself inactive, if wetted with a solution of 1 part  $H_2O_2$  to 500,000 parts water, and hung in a warm room to dry, when placed in contact with a plate for a couple of hours and developed, gives a distinct picture.

Certain metals and organic substances under certain conditions act on the plate.  $H_2O_2$  acts, under the same conditions, in the same way. The action of metals and terpenes is unable to pass through glass, mica, selenite, &c., but passes through gelatine, celluloid, gutta-percha, india-rubber, &c.  $H_2O_2$  acts in exactly the same way. They agree perfectly. Of tests for hydrogen peroxide, that with titanous acid dissolved in sulphuric acid is exceedingly delicate. This gives an orange-yellow colour with  $H_2O_2$ . Dr. Wurster's tetramethyl-paraphenyl-enediamine paper is also good, giving a deep blue colouration.

Is  $H_2O_2$  likely to be present in all the different cases where action on the sensitive plate occurs? First, in regard to the metals: The list of active metals, in the order of their activity, is magnesium, cadmium, zinc, nickel, aluminium, lead, cobalt, bismuth, tin. These are certainly the metals which, in the presence of oxygen, would decompose water and form  $H_2O_2$  :—

As a confirmation that  $H_2O_2$  is formed when these metals oxidise in moist air pieces of tetra paper were moistened and laid on bright surfaces of metal. The blue colour was obtained, varying in intensity in the order given. If the metal is supplied with more moisture, more action takes place. Two pieces of polished zinc were placed in contact with two plates and placed in two iron boxes, one absolutely dry and kept so with calcium chloride, the other kept moist under a bell jar. Through the first was drawn a current of perfectly dry air; through the second moist air was allowed to pass. On development, the first plate showed no image whatever; the second was quite distinct.

All organic bodies which act belong to the terpenes, which, when oxidising, generate  $H_2O_2$ . Already organized bodies do not act. Ordinary turpentine is very active. Most essential oils, as bergamot, peppermint, pine, lemon, &c., are active bodies. These are all terpenes, and are characterised by a strong odour. All vegetable bodies having a strong smell are capable of acting on the plate. Eau-de-Cologne gives a good picture. Thus, the plate is a test for all these bodies, and, as the action is cumulative, it may compete with the sense of smell. Vegetable oils, as linseed, &c., are quite active. Mineral oils, as benzole, naphthalene, phenol, aldehyde, &c., are not active. Hence all organic bodies capable of acting on plate give rise to  $H_2O_2$  when oxidised in moist air.

The speed of transmission through gelatine, rubber, &c., depends on the thickness.

How does the peroxide penetrate the gelatine? Not by diffusion, for hydrogen will not diffuse through it. It must be by a process of dissolving or feebly combining with it and, thus travelling through, escaping on the other side. That the action is of this nature is probable from this example: A sheet of gelatine, about  $\frac{1}{16}$  of an inch thick, was placed over a two per cent. solution  $H_2O_2$  and, resting on it, a plate allowed to remain twenty minutes. On developing it no picture was found. Immediately on removing this first plate a second was put in its place and allowed to remain twenty minutes. This gave a faint picture. A third was darker, and a fourth still darker, but five, six, and seven were, so far as the eye could judge, of the same density. Thus the amount of peroxide given off from the surface increased for one hour and twenty minutes, then the action became constant. The same thing occurs if zinc be used in place of  $H_2O_2$ . If a thin sheet of gelatine be laid on a piece of zinc and allowed to remain there a week, on placing above it a sensitive plate an image will be formed in from one-third to one-fourth the time required if previous exposure had not taken place.

GEORGE D. FIRMIN.

## ADUROL-HAUFF.

MESSRS. FUERST BROS., of 17, Philpot-lane, E.C., send us the following latest formulae for the use of Adurol-Hauff :—

### I.—SEPARATE DEVELOPER.

A.	
Adurol.....	10 grammes or 85 grains.
Sulphite of sodium (cryst.) .....	80 " " 1½ ounces.
Water .....	500 c. c. " 10 "
B.	
Carbonate of potash.....	60 grammes or 1½ ounces.
Water .....	500 c. c. " 10 "

For studio work and snap-shots take 1 part of A, 1 part of B.

For time exposures outdoor take 1 part of A, 1 part of B, 1 part of water.

### II.—ONE-SOLUTION (CONCENTRATED) DEVELOPER.

Sulphite of sodium (cryst.).....	200 grammes or 4 ounces.
Carbonate of potash.....	150 " " 3 "
Water .....	500 c. c. " 10 "
after all having been dissolved	
Adurol.....	25 grammes or ½ ounce.

For studio work and snap-shots take 1 part with 3 parts of water.

For time exposures outdoor take 1 part with 5 parts of water.

For plates inclined to fog add 10 to 15 drops of a ten per cent. bromide of potassium solution to each 4 ounces of developer ready for use, or add from the beginning 1 gramme (resp. 9 grains) of bromide of potassium cryst. to Solution B (I.), or 2½ grammes (resp. 22 grains) to the concentrated developer (II.).

The image appears in from 15 to 20 seconds, and is completely developed in 4 to 5 minutes.

Over-exposures can be rectified by adding bromide of potassium (1 : 10), or by using developer which has done service before.

If specially vigorous density and rapid development are desired, increase the addition of carbonate of potash in Solution B to 100 grammes (resp. 2 ounces), or dilute less the concentrated developer (II.).

The negatives are fixed in an acid fixing bath.

## SUGAR FOR RETARDING THE DEVELOPMENT OF VELOX.

DR. LEO BAEKELAND, who, we believe, is responsible for the preparation of Velox papers, contributes the following article on the above subject to an American contemporary :—

"The objection has often been made that the development of ordinary Velox is so very rapid as to give considerable trouble to the beginner. If one endeavours to make the image appear slower by diluting the developer, it often happens that the blacks have a greenish appearance. Special Velox papers are not open to this objection, for the reason that they can be developed with weaker developers, and can stand more bromide in the developer, still giving good, rich blacks. But special Velox papers can only be used with good strong negatives, and this is the reason why ordinary Velox is always preferred for such negatives as are too thin or too soft to yield good prints with other printing processes.

"Some time ago, Mr. Faraday West, of Point Elizabeth, South Africa, who used Velox continually, wrote us that he was able to slacken the development of Carbon Velox by adding sugar to the developer, without losing the rich colour of the black in the image. We submitted this method to a thorough trial, using variable quantities of sugar, and the result of our experiments shows that sugar is a very valuable agent for making the development of Velox prints much slower. The developer restrained with the sugar not only gives just as good blacks as if a quicker developer were used, but the developing power of the solution,

namely, the amount of prints which can be developed with a given amount of developer, remains the same. The action of the sugar seems to be an entirely physical one, by retarding the penetration of the developing agent into the sensitive film.

"Bromide of potassium, on the contrary, is a chemical restrainer, and that is undoubtedly the reason why it affects the colour of the resulting print, while sugar does not. This is why sugar cannot be used as a substitute for bromide of potassium for ensuring pure whites. For the latter purpose a small amount of bromide of potassium will always be necessary. We made our experiment with the regular M. Q. formula, and noted the following:—

"A normal solution will develop a Carbon Velox print in about five seconds. After adding to four ounces (about 100 c. c.) of same, one teaspoonful granulated sugar, the development slackened down to about ten seconds. Two teaspoonfuls increased the same to twenty seconds, and four teaspoonfuls increased the same to one minute. By adding seven teaspoonfuls, development was retarded to such an extent as to take five minutes, and, what is most remarkable, the blacks of the resulting image had no greenish tint.

"The amounts are given above in teaspoonfuls, but each teaspoonful corresponds to about one-third of an ounce, or nine grammes. We made similar experiments with glycerine, but did not obtain good results."

### THE APPARENT SIZE OF THE SUN.

[Popular Astronomy.]

ALL who have had occasion to examine the celestial sphere, in company with others, have noticed the wide differences in the estimated distances between any two bodies in that sphere as seen by different observers. Of course, a brief period of observation, with any correct thought of the true relations between the bodies apparently scattered over the concave serves to eliminate from the mind all recognition of distances other than angular. But a class of tyros is likely to make some very remarkable queries, such as asking the name of "that star about three feet below the moon," a distance so entirely obvious to the inquirer that he is perhaps greatly astonished to be assured by the general voice of the rest of the class that it looks as if it were ten or a dozen feet distant.

Evidently these variations in apparent distance are due to an unrecognised difference in the estimated distance of the celestial vault from the eye, unrecognised, probably, on account of the absence of all intervening objects serving the observer semi-unconsciously as standards of measurement. But an experience of twenty-five years with classes of youth inexperienced in such observations has led me to believe that the wide differences in these estimates can be explained by reference to a principle not unlike that underlying the errors which we are likely to make in terrestrial observations when all intervening objects are too unfamiliar to afford a satisfactory basis of comparison, and when changed atmospheric conditions invalidate our judgment resting on the clearness or dimness of vision.

I recall a visit to an isolated New Hampshire peak, where the barren rocks afforded no standards of comparison of known size, but allowed me to be deceived by the unusually clear atmosphere, so that I burdened myself with a load of wood designed for a fire upon the summit of a slightly more elevated peak apparently less than half a mile distant; but, after wearying myself with the load while travelling more than half that distance, and proceeding unburdened nearly as much farther, I secured a second supply, which in turn proved almost too much for my endurance before reaching the peak, where previous experience had warned me that fuel would be sadly needed.

So, too, having removed from the Atlantic coast, where my previous life had been spent, to a region of broader outlook and clearer atmosphere in Ohio, I found, while travelling along the unfamiliar level roads, that I was likely to consider men who were approaching me hardly larger than children of a dozen years, until, after an unexpectedly long approach, the error in judgment was revealed; and it required months of residence to enable me to acquire the ability to estimate with reasonable accuracy the distance to some place clearly in view, but as yet unvisited by me.

Possibly a fly moving across a neighbouring window gives, at first glance, a pang of righteous indignation directed towards the neighbour's hens and their proneness to cultivate our garden, a feeling quickly succeeded by the peculiar chagrin caused by the recognition of our erroneous estimate of distance.

In observations of the heavenly bodies the conditions are such as make such errors especially probable, while all basis for the correction of the first impression received is either lacking, or is of such a character as requires more or less comparison and reasoning. Hence it results, I believe, that at a very early age children form their conceptions of the distance to the overhanging vault dependent upon their knowledge of the objects associated in their vision with the more distant bodies apparently located in that arched canopy. I recollect one small lad who, like most young boys, probably saw the sun rise much less frequently than it passed from his vision behind, or nearly behind, the barn of the man who each day furnished the family supply of milk. He saw the sun disappear there at the distance of forty or fifty rods every evening,

and in the morning it was revealed working its way upward from the other side of the glen. So this boy evolved from some part of his interior consciousness the firm conviction that the milkman's son, Will, every morning bore the luminary, which had settled down to rest at his father's barn the evening before, back across the glen in the wheelbarrow which so often brought him the expected milk. I never had an opportunity, after learning this somewhat peculiar solar theory, when I might question its originator concerning the dimensions of the sun permitted by his scheme; but evidently it was only sufficiently large to make a suitable load for the familiar wheelbarrow; and, if the lad's estimate conformed to the principle which I have been led to accept by the very numerous inquiries which I have made of the members of classes coming under my instruction, the sun in that boy's thought occupied scarcely more room than the half-dozen little family milk cans which constituted the usual burden of that vehicle.

The inquiries which, as I have said, I have been making for so long a time, have been especially directed to the apparent size of the sun and moon; and, because to most eyes the moon seems to differ at different times more than the sun, of late my attention has been more particularly directed to reports about the brighter luminary. I have found that with different observers the apparent size of the sun varies from the size of a large wheel, afterward more definitely described as six feet or more in diameter, to the size of a silver dollar. This last estimate, however, has been presented only during the past year or two, and therefore I was at first naturally inclined to ascribe this new opinion to an increased estimate of the size of the silver dollar due to political considerations; but, further inquiry developing the fact that this unusually small estimate was confined to scholars coming from the same class of the same high school, that they had talked the matter over together to a considerable extent, and that sometimes it seemed to them much larger than that, the smaller appearance being only occasional, I was forced to the conclusion that there had been such unauthorised consultation as disqualified those young persons for jurors in the case.

Rejecting those connected estimates, I have found no estimate smaller than the top of a coffee-cup, or, on further questioning, between three and four inches across. From this size, or a little larger, to nearly or quite four feet in diameter, the estimates varied in nearly every class. The larger conceptions have been only rarely presented. The largest one, of six feet or more, was that of a young man whose earliest recollection of the sun was of seeing it sink behind the distant waves of the Pacific. My own early ideas of the sun I easily recall. I mentally fitted it to the top of my mother's best coffee-cups, a trifle larger than those in ordinary use. The home of my early days was amid the New England hills, where the morning sun appeared over a knoll perhaps twenty-five rods from the door, while in the evening it sank behind a hill a little more distant, but still very near.

The principle suggested by these extreme cases I have found to be sustained by a very large majority of the cases in which I have made made inquiry. Each class of students generally contains some who have formed no definite conception of the size of the sun. These students are likely to be among the number of those who have no definite recollection of the places of most frequent observation of the sun in their early years. Not infrequently their homes seem to have been often changed. Very rarely can they tell whether their first experiences were of the sun's rising and setting behind near or distant objects.

But among those who at the time of reporting have a distinct judgment of the apparent size of the sun, or, if that has been displaced by a correct angular conception, still are able to recall their previous estimate, and who also remember the conditions under which their unschooled vision was attracted by its appearance, among these, usually comprising about half of the class, the exceptions are rare to the rule that the estimate of apparent size varies as the distance of the horizon behind which the sun rose or set. It is especially marked that the average estimate of size is much smaller among New England youth reared amidst its hills than with those whose vision made first acquaintance with the broader fields or perhaps prairies of the West.

One other cause I suspect to have an influence upon this conception of size, although my investigations have been too nearly confined to the students under my instruction to furnish the careful comparison necessary to justify a decided opinion. But a limited number of examples has led me to think it not improbable that heredity has some weight here; although, of course, it is difficult to separate this effect, if it really exists, from results similar in character due to unconscious education of the child by the parent.

CHARLES H. CHANDLER.

College, Ripon, Wisconsin.

### EVOLUTION OF INVENTIONS.

THE crude devices of primitive man were improved by successive inventions, says Professor Cleveland Abbe, in an address recently delivered to the Franklin Institute. In the history of invention, properly so called, the simple collocation and juxtaposition of two ideas is often the critical matter. It is not science, or study, or art—it is simply the happy accident that brings some one's mind two thoughts that are suddenly seen by the inventor to have an important relation to each other

hitherto unsuspected. For instance, some one is anxiously looking about for a pigment that will produce a special tint of colour. He is wandering along the roadside and sees the colour he needs in a piece of stone or discolouring a ledge of rock. If his mind is ready to receive the suggestion, it becomes seed sown in good ground. The idea of grinding that stone into pigment immediately occurs to him. He proceeds to experiment, and not only grinds, but oxidises and even roasts the stone. The invention was a matter of suggestions to the inquiring seeker, but the art was an application of physical and chemical science. Man's needs have stimulated him to discover and invent. Those who enjoyed the best surrounding have generally brought forth the best results. Those nations and individuals who were unfortunate as to climate, soil, vegetation, minerals, water power, &c., those who had neither stimuli nor opportunities, did little. In proportion as we to-day associate ourselves with the highest science, we bring forth the best inventions and manufactures. Some one asks why we cannot make a steamboat that will go fifty miles an hour by the use of the screw propeller. The idea is good, but it is a mere matter of imagination, a dream, a useless suggestion until all the resources of physics and mechanics have been combined to evolve the modern high-speed vessel. Professor S. F. B. Morse was an artist, but was also seeking to make some great invention. The idea of communication by means of electricity, with the speed of thought, early took possession of his mind, and he was always on the look-out for some method of realising the indefinite hope that haunted him. Ten years were spent in making every conceivable combination of electrical devices, but nothing came of them. At length Dr. L. D. Gale suggested that Joseph Henry's recent researches on the electro-magnet be put to use. That distinguished scientist was consulted at Princeton, and immediately it was found that the laws that he had discovered in relation to electricity and magnetism, and the apparatus that he had made, were those appropriate to the Morse telegraph; that, in fact, he had one already at work. Even if you do not agree that we ought to speak of the "Henry telegraph" and the "Morse alphabet," you will at least grant that every step in telegraphy, from its beginning to the modern perfection of the art, has only become possible by means of the knowledge resulting from investigations conducted by scientists, or by inventors who had to become scientific investigators before they could complete their work.

#### THE CITY AND GUILDS INSTITUTE EXAMINATIONS IN PHOTOGRAPHY.

We have received from the publishers, Messrs. Whittaker & Co., of Paternoster-square, E.C., the programme of Technological Examinations to be held by the City and Guilds of London Institute during the Session 1899-1900. We extract the Syllabus relating to photography. The acting examiners are Mr. C. H. Bothamley and Mr. J. D. Geddes.

##### PHOTOGRAPHY.

The Examination in Photography will consist of two parts:—Section A, Pure Photography, and Section B, Photo-mechanical Processes. Candidates may be examined in either of these two sections.

##### ORDINARY GRADE.

The Examination in the Ordinary Grade of either section will consist of a *Practical* and a *Written* Examination.

No Candidate will be admitted to the Written Examination who has not previously passed the Practical Examination.

To enable Candidates to qualify for the Written Examination in the Ordinary Grade, Local Practical Examinations will be held at convenient times in the Session preceding the Written Examination. A Practical Examination may be held in any town where there is a class registered by the Institute, or in such other places, distant ten miles from the class, where at least five Candidates notify, through the Local Secretary, their wish to be examined. The Local Examinations will be held under the personal supervision of Examiners appointed by the Institute. The date at which a Local Examination is to be held may be fixed at any time between January 1 and March 3 that may be arranged between the Secretary of the Local Committee and the Local Examiner, provided that at least fourteen days' notice is given to the Institute of the day fixed for such Local Examination; and the Local Secretary will be required to forward to the Institute, within eight days after the holding of such Examination, under the signature of the Local Examiner, the names of any Candidates who may have satisfied the Examiner of their practical knowledge of photography.

The Candidate for the Practical Examination in either section may elect to make his negative in collodion or gelatine, and his print may be produced by any of the methods in ordinary use. He will also be allowed to supply, if he so desire, his own apparatus, chemicals, &c., or he may use those provided by the Local Examiner. The fee for the Practical Examination only will be 2s. 6d.

##### SECTION A.—PURE PHOTOGRAPHY.

I. *Syllabus*.—(1.) The Practical Examination will include the following tests:—To focus, expose, and develop a negative of a person or landscape; to print, tone, fix, and mount an ordinary print.

(2.) The Written Examination will include questions founded on such subjects as the following:—

1. The elements of Photographic Optics. The Photographic Camera and its adjuncts, lenses, diaphragms, shutters, shades, &c.
2. A general knowledge of the practice and theory of the wet-plate process.
3. The practice and theory of the gelatine dry-plate process; the composition of and defects in gelatine dry plates.
4. Various methods of fixing, developing, intensifying, and reducing negatives, with a general knowledge of the chemicals employed.
5. Silver printing, including vignetting and printing in clouds, toning, and fixing.
6. Retouching and spotting; mounting prints.
7. The lighting of the dark room.
8. The studio and the lighting of the sitter.

##### SECTION B.—PHOTO-MECHANICAL PROCESS.

(1.) The Practical Examination will include the following tests:—

To focus, expose, and develop a negative of a drawing in line or wash; to prepare or etch a zinc or copper plate (a) for a process block, (b) for a photogravure plate; to make a collotype plate or a photo-litho transfer.

(2.) The Written Examination will include questions founded on the following subjects:—

1. Cameras and lenses for copying and process work, ruled screens, prisms, reversing mirrors, the appliances in ordinary use for electric and artificial lighting for photographic purposes, and the apparatus employed in photo-mechanical processes.
2. A practical knowledge of collodion (wet and dry), and gelatine dry-plate photography.
3. A general knowledge of various methods of developing, fixing, intensifying, and reducing negatives.
4. A general knowledge of the properties of gelatine, albumen, fish glue, bitumen, resin, inks, etching solutions, and other chemicals and materials used in photo-mechanical work.

The principles and practice of at least two of the following processes:—

5. Photogravure.
6. Block-making—line, half-tone, and three-colour.
7. Photo-lithography.
8. Collotype.

##### HONOURS GRADE.

Candidates for Honours in either Section must have previously passed in the Ordinary Grade of that Section.

The Honours Examination is both Written and Practical.

Candidates in either Section may select the particular branch of practical work in which they desire to be examined.

In order that Candidates may know what apparatus and material they will be required to provide for the Practical part of the Examination, full information as to the practical tests may be obtained from the Examiner on Friday, May 4, for the Examination to be held on the following day.

For the year 1900, Practical Examinations will be held in London only, unless ten Candidates at least apply to be examined in the same Section (A or B) at some other centre.

The fee for the Honours Examination (Written and Practical) in either Section is 3s. 6d.

##### SECTION A.—PURE PHOTOGRAPHY.

(1.) *Written Examination*.—Candidates will be expected to answer more difficult questions in some of the subjects for the Ordinary Grade, and, in addition, a knowledge will be required of—

1. The theory of the photographic image, of development, fixing, intensification, and reduction.
2. The theory of light as applied to photography, including a general knowledge of spectrum and orthochromatic photography.
3. The principles of photographic optics.
4. The theory and practical use of sensitometers for testing the speed and gradation of plates, and their uses in printing processes.
5. The general principles of various negative processes which have been employed at different times.
6. Platinotype, carbon, and pigment printing, printing on argentic bromide papers; enamels.
7. Enlarging and making lantern slides in the camera.
8. Applications of photography to scientific purposes.

(2.) *Practical Examination*.—Candidates may be examined in—(a) Studio Work; (b) Copying or Reproduction; or (c) Landscape and Architecture. They will be required to show proficiency in conducting any of the following practical operations appertaining to the branch selected:—

1. To take in a studio quarter-plate gelatine negative of some object to be indicated.
2. To take an artistic portrait.
3. To print, tone, fix, and mount a silver, platinotype, or carbon print.
4. To test a sample of glass or fabric to be used in lighting the dark room.
5. To test the sensitiveness and gradation of a plate.

6. To find the focus of a lens either corrected or uncorrected.
  7. To copy an engraving for a lithographic transfer.
  8. To make an enlargement from quarter-plate.
  9. To make a lantern slide by contact.
  10. To make in the camera a lantern slide from a negative.
- The Practical Examination will be held on Saturday, May 5, between 1.30 and 7, and at other times, if found necessary.

#### SECTION B.—PHOTO-MECHANICAL PROCESSES.

(1.) *Written Examination.*—Candidates will be expected to answer more difficult questions in some of the subjects of the Ordinary Grade, and, in addition, to show a practical knowledge of the principles and operations in one or more of the following processes:—

1. Photogravure.
2. Line negatives and line blocks.
3. Half-tone negatives and half-tone blocks.
4. Chromo-typography (negatives and blocks for three-colour process).
5. Photo-lithography.
6. Collotype.

(2.) *Practical Examination.*—Candidates may be required to show proficiency in practical operations in one or more of the above processes, numbered 1, 2, 3, 4, 5, 6, including the preparation of negatives suitable for each class of work, from (a) pictures in colour, (b) drawings in monochrome, (c) originals in black and in tints, (d) natural objects.

The Practical Examination will be held on Saturday, May 5, between 1.30 and 7, and at other times if found necessary.

The Written Examinations in the Ordinary and Honours Grades will be held on Wednesday, May 2, from 7 to 10.

II. *Full Technological Certificate.*—Certificates are awarded on the results of each of the above examinations. For the full Technological Certificate, the candidate must qualify as stated in Rules 41, 42.

III. *Works of Reference.*—For the Ordinary Grade: *Chemistry of Photography*, Meldola (Macmillan); *Instruction in Photography*, Abney (Piper & Carter); *Manual of Photography*, Hepworth; *Practice of Photography*, Chapman Jones (Iliffe); *Art and Practice of Silver Printing*, Abney and Robinson (Piper & Carter); *Materia Photographica*, Leaper (Iliffe). For Honours, in addition to the foregoing: *Optics of Photography*, Traill Taylor; *Treatise on Photography*, Abney (Longmans); *The Chemical Effect of the Spectrum*, Eder; *Collotype and Photo-lithography*, Schnauss (Iliffe); *Photogravure*, Wilkinson (Iliffe); *La Photographie des Objets Colorés*, Vogel (Paris, Gauthier-Villars); *La Platinotypie*, Pizzighelli and Hübl (Paris, Gauthier-Villars); *La Photographie*, by A. Davanne (Paris); *Platinotypie*, by Abney and Clark (London); *Modern Heliographic Processes*, Ernst Liezke (Nostrand Co., New York); *Photo-engraving, Half-tone Enamel Process*, Whittell (Socvell Co., New York); *The Half-tone Process*, Verfaesser (Percy Lund); *Half-tone on the American Basis*, Cronenberg and Gamble (Percy Lund); *Photo-engraving*, Farquhar (Dawbarn & Ward); *Photo-lithography*, Frits and Wall (Dawbarn & Ward).

#### THE BRITISH ASSOCIATION.

THE British Association meets at Dover on September 13, under the presidency of Sir Michael Foster, Sec. R.S. The members of the French Association will visit Dover on September 16, and the members of the British Association are invited to visit Boulogne on the following Thursday. It is anticipated that the gathering will be memorable by the large attendance of the most eminent men of science in America and on the Continent. The Mayors and Corporations of Dover and Canterbury, the military authorities of the South-Eastern District, and the leading scientific and educational institutions, will take part in the entertainment of the Association. The Castle at Dover and National Harbour Works will be open for inspection during the meeting. The first general meeting will be held at the Connaught Hall on Wednesday, September 13, when Sir Michael Foster will assume the presidency in succession to Sir William Crookes, and deliver his Presidential address. On the following evening there will be a *soirée* in the School of Art, and on the Friday evening Professor Charles Ritchet will deliver an address on "La Vibration Nerveuse." The professor next evening will discourse on "The Centenary of the Electric Current." In the Mathematical and Physical Science Section Professor J. H. Poynting will preside; in the Chemistry Section the president will be Mr. Horace T. Brown; and the presidents in the other sections will be: Geology, Sir Archibald Geikie; Zoology, Mr. Adam Sedgwick; Geography, Sir John Murray; Economic Science and Statistics, Professor Henry Higgs; Mechanical Science, Sir W. H. White, Chief Constructor of her Majesty's Navy; Anthropology, Mr. C. H. Read; Physiology, Mr. J. N. Langley; Botany, Sir George King; conference of delegates and corresponding societies, Rev. T. R. R. Stebbing. A special feature of the Association will be demonstrations of Signor Marconi's wireless telegraphy, and the Rev. Mr. Bacon, it is anticipated, will give an address on his recent balloon experiments.

#### SOLILOQUY IN A DARK ROOM.

*Punch* has commenced the publication of a series of soliloquies "recorded by Mr. Punch's phonograph." The first is entitled, "In a Dark Room:—"

"There, everything's ready, I think—developer, 'hypo' water—so out goes the light. Perfectly simple to develop one's own films; far better and cheaper than sending them to Westman's. . . . Night light in my red lamp seems a bit feeble—hope to goodness it won't go out. Now I must unroll the film. . . . Hang the stuff, how beastly curly it is. . . . Wonder if I'm cutting it at the right place? Must chance it. Now then, where's that book of directions? . . . Bless me if I haven't left it downstairs, and, of course, if I open the door now, all the film will be ruined! . . . However, I dare say I can remember most of it. . . . Let's see, was it two parts of 'developer A' and two parts of 'B,' or two of 'A' and one of 'B'? . . . Something's coming already, black spots are appearing on the film. . . . I believe that's Kate, or is it a view of the church? . . . Hello, there's some one—what? eh? *What the dickens am I doing in your dressing-room?* Developing photographs, and I chose it because it has shutters. . . . No, you can't come in. *Time to dress, as you're dining out?* Well, you should have thought of that before. . . . Don't do that, you idiot, you'll burst the door open. . . . *Just what you mean to do!* Oh, nonsense, you'll spoil all my photos—ruin them! . . . Yes, I'll be as quick as possible. . . . Eh? Yes, they're coming out splendidly, *splendidly*. Do go away, please! . . . Confound that fellow Jack, probably he's made me spoil the lot. . . . Wonder how long ago I put this lot in the fixing bath before he came and made that row? . . . But surely I ought to have fixed them first thing? Wish I had that book here. Well, I'll try fixing these before I develop them. . . . Dare say either way will be equally good. . . . Hello, here's another bottle, labelled 'Bromide of Potassium.' . . . Wonder when *that* ought to be used? . . . Let's see, it's a sedative, isn't it? Doctors prescribe it for 'nerves,' so I'll put it in the fixing bath. . . . Wish this red lamp would give more light. . . . I do believe it's going out! It is!! . . . And here I am in pitch darkness, with some of the films fixing and some developing, and—There goes the developer over Jack's hair-brushes! Where are those beastly matches? . . . Thank goodness, I've got a candle lighted at last. . . . I declare, all the film is coal-black, and not a sign of a picture on any of it! And I promised Kate half-a-dozen copies of her portrait! . . . Almost makes me inclined to chuck photography altogether. Any how, if I 'press the button' in future, I'll be jolly careful that some one else 'does the rest!'"

#### THE QUEEN AND THE PHOTOGRAPHER.

A few days ago the newspapers reported the circumstance of a gentleman handing a petition to the Queen while Her Majesty was out driving. The gentleman in question was a photographer, and we are indebted to the *Daily Chronicle* for the following particulars of the incident:—

Mr. Heinrich Schmarr, who carries on business as a photographic artist and jeweller at 3, 4, and 5, Tottenham Court-road, is one of those tradesmen who will soon be dispossessed by reason of the improvements which are very shortly to be made at the western corner of that well-known thoroughfare, and for some time past he has been in litigation with the Council as to the terms upon which his premises should be taken over, the result being a decision in the Sheriff's Court to which he has taken serious objection, although he was awarded compensation to the extent of 1000*l*.

Mr. Schmarr has returned to London after his somewhat exciting experiences at Osborne, and was seen by a *Daily Chronicle* representative, to whom he explained the position of affairs, and the reasons which led him to adopt a proceeding which, however orthodox it may be in the Fatherland, is not regarded with favour in this country. It appeared from his statement that he is a native of Frankfort-on-the-Maine, twenty-six years of age, and that five years ago he took over the lease of the premises he now occupies, expending a sum of 2500*l*. on stock, and eventually working up a business which he describes as of a very satisfactory character. Then the Council came along with a notice to quit, and hence the trouble. All he wanted, said Mr. Schmarr, was to be replaced in a position suitable for his business, but in the end, at a time when he was indisposed, the matter was settled so far as the Council was concerned.

Mr. Schmarr was not, however, satisfied, and, failing any other means of redress, he conceived the idea of placing his case before the Queen herself.

"I went down to Cowes on Thursday last," said he, "and stayed at the Fountain Hotel. On Monday I went to Kingston Cottage, at Whippingham, and prepared a letter to the Princess of Battenberg, which I found I could not deliver. I then wrote one to the Queen, giving both my London and local address, and asking very respectfully that Her Majesty would order further inquiry into my case. I was just returning from a walk when I heard the Queen's carriage approaching, and saw that Her Majesty was accompanied by two ladies. As the carriage came up to me, after passing through one of the gates, I took off my hat and made an obeisance, and said, 'I beg your pardon, your Majesty.'"

At the same time I took the letter from my breast pocket, and was about to hand it to the Queen, when the coachman, being perhaps alarmed, drove on rather sharply, and I had to throw the letter into the carriage. I heard the Queen say, "What is it?" and then they drove on.

"I returned to my lodgings, and it was nearly two hours afterwards that Superintendent Fraser and Detective Force came to me and said a gentleman wanted to see me at Osborne. I asked them was I under arrest, and they said No; I could walk as I liked. At Osborne I had to answer a lot of questions, and it was even suggested, as I was a bit excited, that I should see a doctor. But in the end I was allowed to return home. I had some more interviews next day, and then Mr. Fraser kindly saw me to the pier, whence I returned home. I did not see that there was anything wrong in what I had done, and I was certainly surprised to find from some of the papers that I was supposed to be an Anarchist."

## Our Editorial Table.

### CONVENTION PHOTOGRAPHS.

WE continue to receive photographic mementoes of the Gloucester Convention. Mr. Gerald Bishop sends us a print from a negative of the picturesque old walter at the New Inn. The subject has given opportunity for the making of a capital photograph. Mr. R. W. Dugdale, the local Hon. Secretary of the Convention, favours us with a large number of architectural studies at Gloucester, Tewkesbury, Tintern, Chepstow, and elsewhere. Some of Mr. Dugdale's pictures are of the very highest order of merit, and all evince the possession of an acute perception of what is beautiful in this class of work. From Mr. Fred Marriott come two clever snap-shots taken aboard a rowing boat on the Wye between Tintern and Chepstow. Story-telling is in progress between the two carsmen, who are not unconnected with the photographic press, and the photographs are full of humour. Half a dozen snap-shots taken at Tewkesbury reach us from Mr. G. W. Webster to illustrate the good qualities of the plates he was using. A Convention without a subsequent reminder of it from Mr. T. A. Scotton of Derby would be hard to imagine. Mr. Scotton sends us some exquisite platinum prints of views taken at Berkeley Castle and elsewhere. The technique of these photographs is faultless throughout. All the gentlemen named have our best thanks.

### SAMPLES OF GLASS FOR ORTHOCHROMATIC PURPOSES.

By J. R. GOTZ, 215, Shaftesbury-avenue, W.C.

MR. GOTZ sends us a number of samples of pot-coloured plate glass suitable for orthochromatic and colour photography. Mr. Gotz remarks: "Several pots of the yellow material have been made before, but I have now added other colours, notably red, which has not, to my knowledge, been obtainable commercially up to now. The glass is sufficiently ground and polished to give undistorted images by reflection or direct vision, and, being very thin, there is no perceptible dispersion or disturbance of the image after the light has passed through a lens.

Examined in the spectroscope, one thickness of glass will, in all but the lightest tints, tone down the complementary colour to the one examined, while two thicknesses will practically eliminate it, so that corrections of colour intensities are easily obtained.

A black pot glass may be useful for making unburnishable mirrors. All colours, except the red, may be obtained in plates up to eight inches square; the red at present is four inches square."

### HOME PORTRAITURE FOR AMATEUR PHOTOGRAPHERS.

By RICHARD PENLAKE. London: L. Upcott Gill, 170 Strand, W.

137 pp. 39 illustrations. Price 2s. 6d.

MR. PENLAKE writes with considerable experience of his subject, and his book should be distinctly helpful to the amateur photographer anxious to improve the quality of his "home" portraiture. As a rule, amateur's "home" portraits are deficient in respect of proper lighting and posing. Who has not had to submit to be "taken" by some aspiring beginner, whose capacity for producing a presentable likeness has been sadly overrated by himself and his ignorant friends? We would make it a penal offence in future for the amateur to take at-home—indoor or outdoor—portraits without having studied some such book as that before us. In the course of a dozen chapters the author enters into the subjects of accessories, posing, outdoor and indoor work, artificial light, retouching, &c., and, by the aid of half-tone and diagrammatic illustrations, manages to clearly convey the meaning of his teachings in the practice of non-studio portraiture, &c. Some of the half-tone illustrations are from rather poor original photographs, but the book as a whole is a good and useful one.

### CATALOGUES RECEIVED.

The Tella Camera Company, Limited, 110, Shaftesbury-avenue, London, W.

THIS neatly printed booklet of thirty-two pages is devoted to an exhaustive description of the Tella flat-film camera, and an enumeration of its points, which are as good as they are numerous. Some satisfactory suggestions as to the selection of a hand camera are given, and there are eight phototypic illustrations from negatives taken in the camera, which amply attest its great practicability. The Tella booklet should be in the possession of all hand-camera users.

The British Finishing Company, Teakwood-buildings, Bradford, Yorks.

THE above firm send us their twenty-page list for the trade only. The Company are enlargers in bromide, carbon, platinum, &c.; artists in oils, water colour, crayons, black-and-white, &c.; printers in silver, bromide, carbon, platinum, &c.; retouchers and general photographic finishers to the trade.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, September 6, at eight o'clock. Discussion: "Is Simultaneous Development and Fixation advisable?"

MESSRS. TENNANT & WARD, publishers, of 289, Fourth-avenue, New York, inform us that the first and second numbers of the *Photo-miniature* ("Modern Lenses" and "The Pose in Portraiture") have reached a second edition.

THE Cripplegate Photographic Society opens its next session on Monday, September 4, at seven p.m., when Messrs. Griffin's representative will give a demonstration on Kachin. Applications for membership of this Society should be addressed to the Hon. Secretary, Mr. Alfred T. Ward, Cripplegate Institute, Golden-lane, E.C.

IN reference to Cosmos's Scotch tour Mr. J. B. MacLachlan, of Blairgowrie, writes: "I was greatly interested in his Scottish notes, but, just for fear he may get too conceited about his country, I write to correct a current error he has fallen into. Vardon is not an Englishman, unless you call a native of the Channel Islands an Englishman."—[We certainly do.—EDS. B. J. P.]

THE *Globe* says that some one has taken a snap-shot of Mercier and Billot entering the Court at Rennes together, and it is said that the picture reveals the interesting fact that "Billot is very decidedly looking the other way." The idea of the snap-shottist is a pretty one. Next session we shall hear of photographers catching Sir William Harcourt beaming fiercely upon Sir Henry Campbell-Bannerman, and of Mr. Labouchere looking the other way when Lord Rosebery crosses the lobby. There will be other sensitive developments.

RUSSIAN WEIGHTS AND MEASURES are the subject of a new regulation recently officially published. According to the *Times*, the Russian pound is fixed as the standard of weight and declared to be equal to 409.512 grammes, a pail or vedro is to hold thirty pounds of distilled water at 161° (Celsius), and a garnietz eight pounds of water. The unit of length is the arshin, equal to 71.12 centimetres. The metric system is to be optional, and may be used on a par with the Russian in commerce in dealing with contracts, accounts, &c., and after mutual agreement by State and municipal authorities. Private persons, however, are to be under no compulsion to use the metric system when dealing with the above-named authorities.

ACCORDING to the *Australian Photographic Review* the Photographic Society of New South Wales is to be congratulated on meeting with a ready response from His Excellency, Lord Beauchamp, to accept the position of Patron to the Society. "We have it on the best authority that Lord Beauchamp is an enthusiastic and successful hand with the camera. The fact of having so distinguished a patron, the Society will be encouraged and stimulated to attain to even greater things than they have accomplished in the past." The *Review* also states that Mr. W. Blow, of the Crown Studios, Sydney, has been successful, after a series of experiments, with both the Ives and Joly processes of colour photography, and will be giving a public demonstration shortly.

JAMES YATES is an itinerant photographer, who has been accustomed to take up his stand on Scarborough sands in the summer. Ten years ago his wife, just before she died from cancer, expressed the desire that she should be buried by the side of her mother at Cundall, Thirsk. Being unable, from financial reasons, to have the body conveyed by rail or horse, Yates quietly took it to Cundall on a hand cart, the wheels of which had been improvised from a photographic van. The distance was about fifty miles. This pathetic story of domestic devotion leaked out, and 26l. 8s. 6½d. was collected and presented to Yates. With this he purchased an improved apparatus. Being a steady man, he has since saved money, and he has just handed to the Scarborough Hospital the sum of 21l., and the balance, 5l. 8s. 6½d., to the local branch of the Salvation Army. Teddy Yates, a son, then of twelve years, who accompanied his father on the melancholy journey, is a member of the crew of H.M.S. *Barfleur*, and another son is a soldier. Yates was left with eight children.

DOUBLE SALTS OF SILVER AND COPPER.—P. Sabatier has prepared an interesting series of double salts of copper and silver, obtained for the most part by the interaction of solution of the silver salt and blue cupric hydrate. Thus, the compound  $3\text{Cu}(\text{OH})_2 \cdot 2\text{AgNO}_3$  is obtained in blue-violet crystals from normal solutions of silver nitrate; from hot concentrated solutions another dicupric salt,  $2\text{Cu}(\text{OH})_2 \cdot 2\text{AgNO}_3$ , separates in bright blue acicular needles. With solutions of silver chlorate and blue cupric hydrate a heavy blue precipitate is obtained, consisting of well-formed microscopic prismatic scales having the composition  $2\text{Cu}(\text{OH})_2 \cdot 2\text{AgClO}_3$ . A sulphate of analogous

composition  $3\text{Cu}(\text{OH})_2\text{SO}_4\text{Ag}_2$  is obtained as microcrystalline inclined prisms; another form in needles, containing three molecules of water, also exists. With silver thioisulphate blue cupric hydrate forms the salt  $2\text{Cu}(\text{OH})_2\text{Ag}_2\text{S}_2\text{O}_8$  as a violet flocculent precipitate. Most of these compounds may also be obtained by the action of silver oxide in solutions of the various cupric salts.—*Compt. Rend.*, 129, 211.

We have received from the Hon. Secretary of the Maritzburg Camera Club, Pietermaritzburg, the following syllabus for the present session: September 1, "Platinotype Printing," by Mr. S. S. Watkinson; 15, "Development Papers and Opals," (second paper), by Mr. T. C. Mitchell; 29, "Outing to Edendale," October 6, "Carbon Printing," by Mr. E. J. Kerby; 20, "Enlarging" (first paper), by Mr. F. J. Lewis. November 3, "Lantern Slides, Dry Plates," by Mr. G. Smith; 17, "Radiography," by Mr. A. Allerston. December 1, "Enlarging" (second paper), by Mr. H. N. Johnson; 15, "Lantern Slides, Wet Plates," by Mr. W. Cohen. January 5, "Flashlight Photography," by Messrs. Mitchell and Swete; 19, "Exhibition of Apparatus and Discussion thereon," by the Club. February 2, "Art Principles Applied to Photography," 16, "Indoor Photography," by Mr. S. S. Watkinson. March 2, "Copying Photographs," by Mr. H. W. Armstrong; 16, "Isochromatic Photography," by Mr. T. K. McAlister. April—, *Conversazione*; 14 to 17, "Proposed Outing to Table Mountain. We must congratulate our South African friends on an excellent bill of intellectual fare.

## Patent News.

THE following applications for Patents were made between August 14 and August 19, 1899:—

DEVELOPING APPARATUS.—No. 16,516. "Improvements in Photographic Developing Apparatus." R. HADDAN. Communicated by W. E. Oddie and W. B. Cozzens.

CINEMATOGRAPH.—No. 16,590. "Improvements in and relating to Cinematographs, Biographs, Mutoscopes, and the like." R. A. FRASER.

EXPOSING DRY PLATES.—No. 16,646. "An Improved Method of Shortening the Time of Exposure of Dry Plates Coated on one side for Röntgen Photographs." G. C. DYMOND. Communicated by Voltchm Elektrizitäts Gesellschaft A.G., Germany.

CAMERAS.—No. 16,877. "Improvements in Magazine Cameras." R. E. PHILLIPS. Communicated by H. D. Haight. Complete specification.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

September.	Name of Society.	Subject.
4.....	Cripplegate Photo. Society .....	Demonstration: Kachin.
4.....	South London .....	{ A Flashlight Demonstration. Rinhold Thiele.
5.....	Gospel Oak .....	{ Demonstration with the Society's Enlarger.
5.....	Hackney .....	{ Microscopical Lantern Projection. Messrs. Drake and Dean.
6.....	Manchester Amateur .....	{ Excursion: Conway. Leader, H. B. Bradley.
6.....	Photographic Club .....	{ Discussion: Is Simultaneous Develop- ment and Fixation advisable?
6.....	West Surrey .....	{ Open Night.
7.....	Hackney .....	{ Excursion: Broxbourne Common. Leader, E. T. Coombes.
9.....	Kingston-on-Thames .....	{ Excursion: Wimbledon Common. Leader, T. W. Wilson.
9.....	South London .....	{ Excursion: Back Waters of the Lea. Leader, Mr. Marshall.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 24.—Mr. H. C. Rapson in the chair.

Mr. T. E. FRESHWATER asked how he could remove drying marks from some of his negatives. He explained that he had set up the negatives, after completion, to dry in an ordinary drying rack. After some hours he found the edges dry, but in the centres the moisture from one negative had condensed on the back of the next. He then removed the negatives to where there was a current of air, and, when they were perfectly dry, found markings corresponding to the different rates of drying, which in some cases were very evident on the prints. He was recommended to give the negatives a prolonged soaking in plain water and to place them to dry where the drying action would be uniform.

Mr. Freshwater said that a negative had been shown to him in which there was what appeared to be an insensitive round spot. On his suggesting that a drop of water or some solution had fallen on it or the plate at some time, the photographer remembered that, while changing plates in a strange dark room, one or two of the plates had become splashed with water from the tap. He had put aside those he had noticed were splashed, but this one must have passed unnoticed.

Mr. A. MACKIE said that with washed collodion emulsion plates, if the drying were commenced rapidly and continued slowly; for instance, if, after coating, the plates were stood on a shelf in the dark room, and, before drying was complete, were put in a rack box, a distinct mark where the drying had been checked always showed.

The CHAIRMAN said the explanation given, in his absence at the last meeting,

of the cause of the defect in the hand-camera negatives shown by him a fortnight ago was not the correct one. He used a magazine hand camera, the plates, after exposure, falling to the bottom of the camera box, which was of wood and blackened. In the centre of the bottom was a disc of brass covering the tripod-screw socket. It was only the first plate exposed which showed any defect, and this was due to the emanations from the wood or the substance used for blacking it, which had caused general fog. The circular spot, where the negative was perfect, occurred where the plate was over the brass disc.

Mr. J. W. HODGES passed round two negatives. They had been in the two sides of the same dark slide. One had, by accident, received two exposures and the other none at all. The plates had been developed, &c., as usual. The latter showed no image, of course; but it was densely fogged everywhere except where the fabric forming the hinge of the shutter covered the plate. In the former the negative seemed to have developed normally except where the hinge of the shutter occurred, and there a band of fog appeared. The action in the one case seemed just the opposite to that in the other.

No one present had any explanation to proffer.

Mr. Hodges also passed round a print on collodio-chloride paper. It had been left in the printing frame and exposed to light for about nine hours, that is to say, about eighteen times as long as was necessary to make an ordinary print. The print showed the subject as a negative. In the shadows, or more transparent parts of the negative from which the print was made, the silver of the paper, under the prolonged action of light, had been reduced in a grey form resembling the reduced silver on a wet-plate negative, and, where the lights or dense parts of the negative had to some extent protected the paper, the reduction was of the usual dark-brown tint.

### PHOTOGRAPHIC CLUB.

AUGUST 23.—Mr. J. W. Mason in the chair.

Mr. E. W. FOXLEE said he had been experimenting with gelatines, and had secured one very striking example, showing the power of a coating of gelatine on a glass plate. He had coated a glass plate with a thick layer of gelatine and allowed it to dry, and the result was that, when the dry film was sprung off, it brought with it flakes from the glass plate. With the ground-glass plates for the collotype process he had often seen very peculiar effects produced in this way, but in this case the ground surface and the substratum used tended to bind more with the gelatine than did the polished surface of the glass used for drying the gelatine upon for his experiments. Different gelatines, he found, produced different characters of splitting, a tough gelatine, for instance, having a distinctive action to that of a brittle gelatine.

The application of this property of the gelatinous bodies to commercial purposes for the production of designs upon glass articles was referred to in the comments which were made upon the specimens passed round by Mr. Foxlee.

Mr. F. Dundas Todd, now visiting London from the United States, was welcomed by the Secretary on behalf of the members, and there ensued a conversational discussion upon the general qualities of several of the newer developing agents.

North Middlesex Photographic Society.—August 21, Mr. H. W. Bennett in the chair.—Mr. F. L. PITHER gave a lecture, entitled,

WHAT TO PHOTOGRAPH, WITH HINTS ON COMPOSITION.

The lecturer said that, in painting, the individuality of the operator influenced the result. This to a great extent was impossible to photographers, but was in some measure attainable; also, painters generally had a definite idea in view. You should determine what pleases you, and aim for that result in your working. The lecturer gave a few rules as to the placing of the principal objects in the picture, and also said that very often the standard sizes of plates did not give the best shape for the picture. He suggested the size 8 to 1, instead of the usual 1 to  $\frac{1}{2}$ ; very often, he said, it would suit the subject better (the lecturer confined himself to remarks on landscape). A good definition of breadth was that it was the reverse of spottiness. The half-tones were the making of a picture, and, for this reason, do not print on absolutely white paper. To illustrate his remarks, he made rough sketches on the blackboard and also referred to a number of engravings hung on the walls. In reply to a question from Mr. MUMMERY as to the position of a principal object in one of the engravings, and as to whether in the original picture the colour had supplied the deficiency? Mr. PITHER said that in treating of colour all these rules relating to black-and-white work went for naught. A painter could balance his picture by making one part warm in tone and another cold, leaving form out of the question. Replying to a question of Mr. LIVETT as to a remark he made about "complexity of focus," the lecturer said it is having two points of light in strong competition. Mr. Pither replied to several more questions, and a very entertaining and instructive lecture was brought to a close.

### FORTHCOMING EXHIBITIONS.

- 1899.
- Sept. 22-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craige, The Camera Club, Charing Cross-road, W.C.
- " 25-Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.
- October 18-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.
- " 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.

Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### COPYRIGHT.

To the EDITORS.

GENTLEMEN,—May I point out to you a glaring piece of piracy of one of my pictures, the late —, by Messrs. —, of London? Some eighteen months ago I was requested to take a group of three generations. I took this, and subsequently got orders for about thirty dozens. I also took on my own account a large head and shoulders photograph of —, and sent the family a few copies for which I did not charge. Some six months or so after, the old gentleman died, and the family ordered about two dozen *cartes-de-visite* of this photograph, and purchased an enlargement I had done on my own account. I did not copyright at the time, but subsequently registered the photograph. Some three months or so ago, was told there were some reproductions of my photograph about the town, and that they were marked proof, and were selling one guinea each. For some weeks I tried to come across one, and also name of firm reproducing same, but did not succeed; but a framer told me he had framed twenty or thirty. Three weeks ago I saw one; it just had "proof" on, no name. I asked Mr. — if he knew anything about it, he said Mr. — asked him if he might make a drawing from the photograph, and thinking there was no harm in it, and not knowing I had registered the photograph, he gave permission, and subsequently purchased some, and gave to his officials. I next wrote to Messrs. — and told them I had come across their reproduction of my picture, which was an infringement of my copyright, and stated that they might have had the courtesy to acknowledge same, and should be glad to receive reply hereon. Mr. —, in reply, stated that he had received permission from Mr. —, therefore he could not understand the meaning of my letter; he applied to me without Mr. —'s permission, he certainly would have asked whether I objected to his making use of my photograph, but, as matters stand, he declined to make himself responsible. He further stated that, owing to my photograph being in the market, he did not dispose of half a dozen copies, and, in consequence, had suffered great loss, and had destroyed plate months ago. I wrote Mr. — on the subject, and, in reply, he says: "I think you are quite right in taking up with Messrs. —, but I would not like you to take extreme measures." After this, of course, I can do nothing, as Messrs. — are very good customers of mine. Mr. — alone took twenty copies of this picture (—'s), and gave same to his clerks' foreman, &c. I wrote Messrs. — and told them they were certainly liable, and that I knew he had supplied twenty copies to Mr. —, but I presumed the five or six they mention would be in addition.

I had several inquiries about my three-guinea enlargements of my picture, and, on the strength of two promises, made two, which I still have by me; those who were going to purchase cancelled their order—they have —'s reproduction.

I suppose mine will be one of very many similar cases brought to your notice.—I am, yours, &c., J. G. G.

### THE CAMERA CLUB EXHIBITION.

To the EDITORS.

GENTLEMEN,—Mr. Maclean, in your issue of the 25th inst., desires to excuse his slovenly criticism in the *Camera Obscura* of the Camera Club Members' Exhibition.

As he commences with an imputation of motives against the Editor of the JOURNAL, it would be perfectly justifiable that his communication should be treated with contempt; however, as this is probably to be attributed to defective education, we must be a little charitable towards him.

Taking his paragraphs *seriatim*, he firstly complains of the want of a catalogue, a most unfortunate remark for him; the writer observed an evident representative of some periodical making notes on a sheet of paper, and remarked to a fellow-member that it was strange the critic should not avail himself of a catalogue of which there were several lying

at the disposal of visitors on the tables in the Club-room, he was subsequently told on inquiry that the visitor was Mr. Maclean.

No absence of catalogue nor any other reason can excuse a critic who, quoting the actual number of a frame containing a landscape picture, proceeds to criticise it adversely as a portrait by a Mr. Beard, who has no portraiture exhibited here.

Mr. Maclean is desirous of throwing his responsibility on Mr. Craigie. Certainly, when I observed Mr. Maclean in the Club-room for a considerable time, he was alone, and Mr. Craigie informs me that he cannot remember having enjoyed the pleasure of a personal introduction to Mr. Maclean, and he has no recollection of having shown any stranger round the walls of the Exhibition, and was also unaware until quite recently that Mr. Beard figured as one of the exhibitors. It therefore seems, to say the least, unlikely that he should have misled Mr. Maclean in the manner stated in his letter.—I am, yours, &c.,

THE WRITER OF THE REVIEW IN THE  
CAMERA CLUB JOURNAL.

Camera Club, Charing Cross-road, W.C., August 26, 1899.

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

G. W. French, Church-street, Wiveliscombe.—Photograph of a cat with wings.

A. Coupe, 48, Wilmslow-road, Withington, Manchester.—Photograph of three boys playing nap.

R. Spurr, South Cliff, Bridlington Quay.—Photograph of Colonel Bridgeford and officers of 2nd V.B. Manchester Regiment.

F. DOWDALL.—The temperature of the developing solution was too high. We have ourselves produced the effect seen in your negatives by such means.

MEDRINGTONS, LIMITED (Liverpool).—Thanks for the print and note, which we have returned. It is a very common case of "mystery photography," of which we possess numerous examples that defy explanation on ordinary grounds.

SENSITISING POST CARDS.—ROGO says: "Could you please say is there any method of sensitising post cards so as to print by artificial light?"—The only thing we can suggest is to coat the cards with a gelatino-bromide emulsion, and, after exposure, develop as bromide papers are developed.

WET-PLATE POSITIVES IN STUDIO.—WET PLATE asks: "Shall be glad to know if it would be possible to do wet-plate positives in studio by flashlight? Am using an old-fashioned Voigtlander lens, without stops. Particulars would much oblige."—Yes, certainly; but a larger quantity of the powder will have to be employed than is the case with gelatine plates.

LESSONS IN MINIATURE PAINTING.—N. W. D. says: "Could you kindly inform me of a reliable photographic artist where I could get lessons in miniature painting and working up black-and-whites? I should like, if possible, to get some one within easy distance of Clapham."—Better consult our advertisement columns. It is strictly against our rule to give an opinion of any particular advertiser's wares or qualifications.

TRANSPARENT LINES ON NEGATIVE.—AJAX says: "Can you tell me the probable cause of the fine transparent lines on the right-hand side of the enclosed negative. The negative is on a Hill-Norris dry-collodion plate, and has been intensified by Monckhoven's process. These lines do not appear until the negative has dried."—The lines are cracks in the collodion film, owing to its contraction while drying after intensification.

COPYRIGHT.—PROF. PHOTOGRAPHY says: "I bought a photograph in London produced by a Parisian photographer. 1. Have I the right to copy same? 2. To make enlargements? 3. Could I sell the same? The photograph is not registered copyright."—1. No, as probably the picture is copyright in France, consequently it is copyright here under the International Law. 2 and 3. Certainly not if the work is copyright.

STAINED VIGNETTES.—H. J. complains that many of his vignettes, of which he sends samples, are stained in the whites. He says that every care is taken in the fixing and washing, and that the stains do not show in prints that are printed solid. The stains proceed from the mounts. The dark surface is partially soluble in water, consequently the moisture in the mount softens it and thus stains the back of the print, and the stain shows through the paper.

PATENT QUERY.—S. P. writes: "I saw a description of an apparatus in one of the back volumes of THE BRITISH JOURNAL OF PHOTOGRAPHY. I have very much improved upon it. Can I now patent it, so that no one else can make it?"—No; but you can patent your improvements upon it, setting forth in the specification distinctly what they are and what you claim as the improvements. Of course, any one will still be at liberty to make the thing as it was described in the JOURNAL.

**FORM FOR SITTERS.**—LANCASTRIAN says: "Would you please write out a form for sitters to sign when the photographs are copyright? I have written several out myself, but they have not been satisfactory to me, and so would be glad if you would suggest one."—In reply: Send us two or three of those you have already written out to see. Probably any one of them is all that is required. If you join the Photographic Copyright Union (see p. 639 of the ALMANAC), which will cost you nothing, the Secretary will possibly supply you with printed forms.

**STUDIO BUILDING.**—CLARIONETTE says: "I am desirous of building (in portable sections) a studio about 18x9 feet in a garden 75x19 feet. I should like to know what regulations there are to be considered. Would plans have to be submitted to district surveyor, and what are the fees, if any? The district is under the Croydon Corporation."—We presume that plans would have to be submitted, but we are not conversant with the by-laws of the Croydon Corporation. Better consult the district surveyor before commencing the work. It may save you a deal of after-trouble and perhaps expense.

**PHOTOGRAPHS OF AN ESTATE FOR SALE.**—A COUNTRY PHOTOGRAPHER writes: "A solicitor here is interested in the sale of an estate, and wants me to take a number of photographs of different parts of it. He says the estate agents told him to instruct the photographer to make the grounds, &c., to look on as large a scale as possible. But how is that to be done?"—Use a lens that will embrace a tolerably wide angle, so that the perspective becomes somewhat violent. In this way, with a very wide-angle lens, a duck pond may be made to look like a small lake, and moderate-size grounds extensive ones.

**COPYRIGHT.**—MIDLANDS writes: "A photographer in this place took some photographs—views of old buildings of interest which are now pulled down, and I know that he made them copyright at the time. He has recently sold this business, and negatives, including these, to the new-comer, and I don't believe—in fact, I know—that the copyright in these has been legally transferred. Am I not at liberty to copy them for sale?"—No; certainly not. If the copyright has not been legally assigned, it is still vested in the one who took the pictures, and he would, no doubt, proceed against you for the piracy.

**OWNERSHIP OF NEGATIVES.**—J. H. V. WATTS says: "Some time ago I was instructed to photograph an old cross in this neighbourhood, for which I received the sum of 10s. 6d. I exposed two plates and delivered two prints. I also made a lantern slide from same, for which I was paid. Now the gentleman for whom I did this work claims the negatives also. Would you kindly answer me as to whether I am the owner of those negatives or not?"—In reply: Yes, the negatives are yours. You contracted to supply prints and lantern slides only, and therefore your client can have no claim upon you for the negatives.

**STAINS ON NEGATIVE.**—HAROLD says: "The enclosed negative is a specimen of a trouble the like of which (although an operator of vast experience in dry plates for over twenty years) I have never seen before. These markings have occurred during the hot weather, and make their appearance during development. I first put it down to allowing developer to remain perhaps a moment on plate while examining it, for it is at this moment these marks appear. Could you, sir, help me out of this trouble?"—The stains appear to be due to carelessness in handling the plates either before or after exposure. One of them bears unmistakable evidence of a finger or thumb mark, probably when the finger was moist with perspiration.

**COPYRIGHT.**—S. says: "To make a lantern slide for my own use, I purpose copying an etching which appeared in a French art journal in 1873. The painter of the picture died over twenty-five years ago. After this lapse of time can the copyright be vested in anybody, and, in making such slide without permission, would there be any infringement on my part?"—If the etching is still copyright in France, it is, under the International Copyright Act, copyright here, and it would be illegal to reproduce it here. The duration of copyright is different in France from what it is in this country. We, personally, are not familiar with the French copyright law. Perhaps some correspondent who is will enlighten the querist.

**STUDIO-BUILDING.**—COLOUR says: "I am erecting a photographic studio; it is well lighted from north. The sides and ceiling are lined with wood. Enclosed are twelve patterns of colours, each numbered on the back. Would you kindly say which number of colour would be most suitable to paint studio walls for purposes of photography? My preference is for colour No. 7, next No. 6; but these colours might not be suitable; if not, would you kindly say which is the right colour? And, again, as to studio curtains, which number of colour would be most suitable for them?"—No. 7 would be a very suitable colour, but we should prefer a little more blue and rather less yellow in it. As for the curtains, No. 10 will be about the most suitable of the fabrics sent.

**CURLING OF COLLODION PRINTS.**—A. C. STRUTT says: "I should be much obliged if you would answer the following question in your next issue. Do you know of any means of preventing collodio-chloride papers from curling up during the operations of washing, toning, and fixing?"—Different plans are recommended for avoiding this trouble with those brands that give it. One of the best is to fill a dish with water, to the depth of half or three-quarters, for the first washing. Place the dry prints face downward in this, one by one, and keep them flat. When all are immersed, draw the bottom one out and lay at top, and so on with the rest. After five or ten minutes of this treatment the prints will have but little tendency to curl. In obstinate cases tolerably hot water may be used in place of cold. If the prints are prevented from curling at the initial stages, they have little tendency to curl afterwards. A solution of alum has been recommended to be used before the prints are washed, but we do not advise its use.

**VALUING A BUSINESS.**—M. L. says: "I should feel obliged if you could inform me upon what basis a photographic business of considerable standing is usually valued. Is it customary to base the estimate upon so many years' purchase of the profits; and, if so, for what period? I quite understand that the stock in trade is taken on a separate valuation, but am doubtful as to the value of the goodwill. I may add that the business is under the direct personal supervision of the principal."—This is a difficult question to answer, as so much depends upon local circumstances—amount of opposition in the neighbourhood, situation, status of the business, amount of returns, prices, length of lease, &c. Perhaps some correspondents will give their ideas on the subject.

**COPYING A COLLODION POSITIVE.**—F. C. says: "I have had sent for copying an old collodion positive. This has gone yellow round edges, and by reflected light it is rather weak-looking. However, I think that everything is in it, and it could be restored; but, as I do not at all understand wet collodion, I should be pleased if you would help me. 1. How shall I proceed to restore the vigour to the positive itself? 2. How would you advise me to make my copy, by reflected or transmitted light? Of course it is a negative by transmitted light."—In reply: 1. Better not tamper with the picture, as in all probability the collodion has become somewhat rotten. 2. Whichever way will yield the best results, and that, of course, we could not give an opinion upon unless we saw the photograph.

**COLLOTYPE PRINTING.**—SABETA says: "I wish to take photographs similar to the enclosed. Could you kindly be of some assistance to me in giving me a few hints as to how to produce them? What particular make of paper to use, and how to produce the black border with name at bottom? I believe it is all done with one exposure on the negative, and that they can be turned out by the hundred very quickly. You might also say how to dry them flat with the fine surface."—The print sent is made by the collotype process, probably printed in a power machine, and glazed with an aqueous solution of lac afterwards. Any work on the collotype process will give you all the desired information. Schnauss's work is a good one. It may be had through Messrs. Dawbarn & Ward, Penrose & Co., Iliffe & Co., or any bookseller.

**GELATINO-CHLORIDE PRINTING.**—H. M. says: "I have been making some gelatino-chloride paper by the formula given by Woodbury, viz.: Water, 8 ounces; silver nitrate,  $\frac{1}{2}$  ounce; Rochelle salts, 20 grains; ammonia chloride, 10 grains; alum, 50 grains; citric acid, 1 drachm; gelatine, 1 ounce. I get good prints and nice tones, but when the prints are drying they go quite dull, although much of the brilliancy returns when quite dry. Can you tell me the reason why this is so, and how it can be avoided? I use Nelson's No. 1 gelatine mixed in equal parts with Coignet's Gold Label. I enclose samples, also a finished print on the paper."—Possibly it may be due to the surfaced paper upon which the emulsion is spread. Try another sample of the raw paper. However, the print sent is very good, and we think more gloss would be offensive to most persons. It is about the average gloss of most P.O.P.'s that are not squeezed on to glass.

**BACKGROUNDS. DEVELOPMENT WITH METOL.**—SEVERN SEA asks: "1. Can you advise me of the best way to attach a canvas background to a hollow tin roller? 2. Also, in developing bromide paper with metol, what is the plan usually adopted in the matter of fixing? If each print is washed and then put in water, the lights get degraded, while other prints are being developed, and, if they are washed in water and then put in hypo as developed, how can equal and perfect fixation be assured?"—In reply: 1. Stitch a piece of stout calico tightly round the roller, leaving an inch or so free; then give it a coat of thin glue. Sew the end of the background to the free piece. 2. Necessarily, the development goes on, to an extent, while the prints are in the water. They should be put into the hypo at once after washing, and each given the same time in the solution; then equal fixation will, of course, be secured in all the prints. Employ a good quantity of the solution.

**ADHESIVES, &c.**—H. C. says: "I should be greatly obliged if you would answer the following queries: 1. What is the best adhesive for mounting glazed prints (I have always been used to burnishing before. I use Le Page's fish glue at present, but wonder if it is injurious to them), and how is dextrine made for use? 2. What is a fifty-grain solution? I notice it in the ALMANAC and recently in the JOURNAL, but cannot understand the term. The following may be of interest to you: I was recently spotting and blocking out a machine, and picked up a penholder in mistake for the brush. I instantly saw my mistake, but the incident caused me to wonder why a pen would not do for the purpose. I put the idea in practice, using a 'J' pen nib, and putting the opaque on the pen with a brush, and found it to work excellently; in fact, I had outlined the machine almost before I knew it. I should think a quill pen would work better, but have not tried it. The pen being hard, one has complete control over it, and avoids shaky lines and straining of eyes, of course. I go round the outline with the brush after, as the pen leaves only a very thin line. Another thing I find useful when the vignetting frames have been caught in a shower is to apply a piece of blotting-paper (under the vignettted) to the glass, which will instantly absorb all spots in a quarter the time a cloth will, and without disarranging the cotton-wool, &c. I have just opened a business at above address, and built a studio as recommended by Messrs. H. P. Robinson and J. Inglis (single slant). It is 28x15 feet, and seems very handy."—In reply: 1. We should prefer either starch paste or a thin solution of gelatine, which is free from acid, such as Nelson's No. 2 soluble. Simply stir the dextrine in cold water till dissolved. We should not advise its use, as commercial dextrine is almost invariably acid. 2. A fifty-grain solution is one that contains fifty grains of the salt, whatever it may be, dissolved in an ounce of water.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The formulæ will be revised where necessary, and the latest de-

partures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

THIS is the season of the year when learned institutions, such as the British Association, professional combinations like the Journalists' and the Naval Architects, and industrial societies such as the Trades Union, take holiday in the country and meet in congress, there to combine the pursuit of pleasure with the discussion of scientific or business affairs of common interest. The Photographic Convention, as is well known, is a law unto itself in this matter, for it prefers not to wait for the holiday months of August or September, but holds its country festival each year in the early part of July. The American Convention is in a line with its British contemporary on this point, and we observe in our Transatlantic exchanges full reports, which, in some cases, extend to thirty or forty pages, of the things that were done at the Celeron meeting, which took place two months ago.

\* \* \*

THOSE of our readers who have attended a British Convention will the more easily perceive the difference which exists

between the conduct of that body and the American gathering if we briefly indicate the salient features of the last meeting of the American Convention at Celeron. Only professional photographers, the manufacturers, and dealers appear to have attended the meeting; the amateur and the scientist seem to severely stay away from American Conventions. The social programme was a full and varied one. There was an excursion and "clambake" (will some American reader kindly tell us what a clambake is?) given by the dealers and manufacturers, an informal "hop," a theatre party, a grand ball, and feast of lanterns, given by the citizens of Jamestown, and other festivities. Evidently the American Conventioneers "do themselves" exceedingly well.

An exhibition of professional work, in which the leading men of the American continent competed, was held during the Convention, and something like sixty awards were made. There appears to be a keen desire to secure a recognition at the hands of the Judges at the American Convention. The business meetings were taken up largely by discussions on matters of interest affecting American professionals as a class, and there was a little art talking, which probably sounded better than it reads. In another part of this week's JOURNAL we give extracts from two discussions which took place, and which sufficiently indicate the tenour of the formal proceedings. On the whole, it appears to us that the American Conventioneers must have a profitable as well as an enjoyable time. They play hard, it is true, but they all appear to be animated by the wish to help and learn from one another, and, if we may judge by what we are told and what we read, the annual Conventions of the Photographers' Association of America, as well as similar but smaller gatherings which are held in individual States, must be productive of a large amount of good to professional photography in the United States.

THE new photographic telescope constructed for the Potsdam Observatory is now complete, and the opening ceremony took place on Saturday, August 26, under the auspices of the German Emperor. The object-glass, aperture 80 cm. (about 31½ inches), is the work of the well-known opticians, Messrs. C. A. Steinheil Söhne, of Munich. The fellow instrument for visual observation, with an aperture of 50 cm. (about 20 inches) was made by the same firm. The Emperor has bestowed the order of the Red Eagle upon Dr. Rudolph Steinheil, the present head of the firm, in recognition of the excellence of his work. We expect shortly to give our readers further particulars of these instruments.

A STRIKING tribute to the value of radiography in medicine and surgery was recently paid by Dr. C. Mansell Moullin, a former President of the Röntgen Society. He points out that the fluorescent screen has now reached such a degree of perfection, that with suitable apparatus the minutest movement of the heart and lungs, and the least change in the action of the diaphragm, can be watched and studied at leisure in the living subject. There is scarcely any change in connexion with the lungs and heart and great vessels which cannot now be seen and photographed, scarcely a disease of the chest or of the organs which it contains, concerning which the most valuable information cannot be obtained. To such an extent has the

fluorescent screen been improved, and so easy has investigation with it been made, that it is probable that some day the examination of a patient's chest with it will be considered as much a matter of routine and as little to be neglected in all doubtful cases as an examination with the stethoscope is at the present time. Valuable as are the indications given by the ophthalmoscope in obscure diseases of the brain, they are not to be compared with those which can be obtained by systematic and skilled use of the fluorescent screen in diseases of the heart and lungs.

It is furthermore stated by Dr. Moullin, whose observations are summarised by *Nature* last week, that the benefit which surgery has derived from the improvements which have been effected in the use of the Röntgen rays during the past year is no less striking than that gained by medicine. As might be expected, the largest proportion and the most striking cases have been furnished by the injuries and diseases of bones and joints. With a well-lit fluorescent screen the nature of an injury can be seen at once, and, what is even more valuable, it is no less easy to ascertain whether a fracture is properly set or a dislocation completely reduced. If the screen is of service to physicians in the diagnosis of intra-thoracic disease, the records of the past year have shown, by numberless instances, that it is no less valuable to surgeons, by enabling them to make sure at a glance that the bones are in their proper relative situation without touching the splints or giving the patient a moment's pain. It will be seen by these observations that the earliest anticipations of the probable value of radiography in surgery and medicine have been fully realised.

THE *Scientific American*, in a recent issue, contained some remarks on accuracy and style in scientific writing which may be commended to the particular attention of that very large number of photographers who record their experiences in print. In no profession, not even in *belles-lettres*, points out our contemporary, is the art of literary expression of such pre-eminent importance as in scientific writing. So much depends upon the accurate use of words, and upon the manner in which they are grouped to convey the author's ideas, that it is surprising how little attention is paid by a large proportion of the writers of scientific articles to literary technique. No doubt, much of the difficulty experienced by the average student in mastering some apparently obscure scientific exposition is due to the author's inability to express himself with that clearness which is so essential to all forms of good writing. Popular science, in the opinion of many, is often a poor kind of science, but it owes no small share of its popularity to the perspicuity and simplicity which has characterised the style of its writers.

No man has greater need of a masterly command of the technique of his language, proceeds our contemporary, than the scientist. He should devote much of his time to analysis in the verbal laboratory, as well as in the chemical and physical, in order that he may habitually select his words and frame his sentences with a careful regard for their fitness to convey exactly and lucidly the thought in his mind.

THE novelist or the essayist undoubtedly has an advantage over the scientific writer, in so far as his subject is apt to be

lighter, more easily followed, and perhaps more fascinating to the average reader. The mental effort of glancing through a novel or light magazine article is less than that of reading a treatise on stellar chemistry or biology; but it is within the power of a brilliant stylist, like Huxley, to render the effort pleasurable, even though the subject-matter be abstruse or, in a popular way, unattractive. The inaccurate use of a word in the one case has but little effect upon the context, and, indeed, may even be unperceived by the reader. In a scientific article, on the other hand, an expression carelessly used may render a whole passage obscure, or completely distort the meaning of a sentence. Hence, as some one has cleverly said, the aim of writing, and especially of scientific writing, is not that one may be understood, but that one may not be misunderstood.

\* \* \*

A GLANCE at our Patent intelligence this week will show that, of the applications there recorded, no less than five are connected with film photography. This may be taken as an indication that the matter of flexible films for photographic purposes is receiving considerable attention at the hands of inventors, especially when viewed in conjunction with the circumstance that two new gelatine stripping films have recently been publicly demonstrated before photographers. It is eighteen years or more since flexible gelatine films were first placed on the market, so that it argues considerable faith in their possibilities on the part of modern inventors and patentees when we find the latter still busy with the subject in the present year of grace.

\* \* \*

THE characteristic energy of the Leeds Camera Club, one of the most useful and hard-working photographic societies in Great Britain, has manifested itself in a new direction by the publication of a syllabus and hand-book for the session 1899-1900. Within the compass of a neatly printed and bound volume of 64 pages a list of the Club's officers, the rules, and particulars of competitions are given, and there are over twenty pages of informative articles on choice of subject, exposure, developers and development, printing processes, gelatino-chloride printing, platinotype, carbon and bromide; but it makes us rub our eyes to note the following belated commendatory reference to the extinct gum-bichromate process: "The gum-bichromate printing process is one for the few, and must not be judged by ordinary photographic standards. A successful result is most satisfying, but in any event the pleasure of trying it and even failing is not altogether disappointing. Wide as it is in its opportunities for control and modification, the working of it yields a splendid study in tone values—not the safest part of a photographer's education."

\* \* \*

FOURTEEN pages of the book are set aside for particulars of the syllabus, in which the names of J. Craig Annan, A. Horsley Hinton, Dr. Llewellyn Morgan, J. W. Wade, T. Morley Brook, T. Manly, J. Bushby, Harold Baker, W. E. Tindall, and others find place as lecturers on interesting subjects during the session. Thirteen portraits and biographies of these gentlemen are given, and the photographs and reading matter are interesting, and, in the latter regard, sometimes amusing. By way of frontispiece to the book there is printed a speaking likeness of the accomplished President of the L.C.C., Mr. W. J. T.

Warren, whom, with his coadjutors, we heartily congratulate on the production of a unique volume in the way of photographic society literature. And to these congratulations we add our best wishes to the Club for a successful session.

\* \* \*

WE understand that the arrangements for the whole of the Lantern Exhibitions for the British Association meetings at Dover next week are to be carried out by Messrs. Newton & Co., of Fleet-street.

#### PERMANENCE OF THE BROMIDE PROCESS.

At a recent meeting of the Photographic Club a very important topic was discussed—"The Permanence of the Bromide Process." This is a subject that is of paramount interest to every photographer, for without question this process is more extensively employed for enlargements at the present time than any other. In fact, it may safely be said that, although the bromide process is of comparatively recent date, there are already more bromide enlargements in existence than there are by all the other processes put together. We mention this merely to illustrate the importance of the subject, for it stands to reason that the public do not go to the expense of an enlargement, however low the price may be, and the cost of a frame for it, unless they expect to get a lasting picture. Therefore it is to the credit of photography and photographers that they get it, and are not supplied with a result, however good it may look at first, that will change in the course of a few years. There is no gainsaying the fact, however, that many bromides have done so, and in even less time than that. But is it the fault of the process, or of those who made the pictures?

The gelatino-bromide process on paper was invented and patented by Mr. J. W. Swan in 1879, consequently it is just twenty years old, and it was worked commercially shortly after its introduction. Therefore it has been sufficiently long in use to test its permanency, or, at least, to the extent of about twenty years; and, if a photograph endures unchanged for that period, it may be fairly assumed that the process by which it is made is not a fugitive one. Gelatino-bromide pictures are in existence, without change, that were made in the earliest days of the process. At the same time it must be borne in mind that there are hundreds of others that have become of a sickly yellow, though we have not yet come across any that have actually faded—the image itself disappeared. This tends to show that it is to the gelatine or the paper—or probably the two combined—that this change is to be attributed.

As some pictures have changed, while others have not in the least, it seems to indicate that it is certainly not the fault of the process, but of those who work it, and with them solely rests the reason for the deterioration. It may, therefore, be well just now to inquire as to the probable cause or causes why some pictures have undergone change. We have frequently seen the process worked on a commercial scale in different houses, where the ferrous oxalate was the only developer employed. This was always used in a more or less acid condition, and, after development, the pictures were immersed in a bath of dilute acid. Then, after a meagre washing, sometimes a mere rinse, they were put direct into the fixing solution. Now, under these conditions, the prints, of course, contain a considerable amount of free acid at the time they

are put into the fixing bath, with the result that the hyposulphite of soda is decomposed, and sulphur and sulphurous acid are set free—to say nothing of complex silver compounds—both in the gelatine film and in the paper. Under such conditions as these it is not at all surprising that some bromide pictures do, after a time, show a change; indeed, it would be more extraordinary if they did not. But this deterioration clearly must not be attributed to the process.

Here is another cause, and a fertile one too, to which a change may be attributed, namely, imperfect fixation. Many photographers, when a silver print fades, put down the cause to imperfect washing; but we unhesitatingly say that, in the majority of cases, both with developed and printed-out pictures, it is more due to faulty fixing than to faulty washing. When a photograph is placed in a solution of hyposulphite of soda, the first action of the latter is to convert the bromide or chloride of silver, whichever it may be, into hyposulphite of silver. This, with excess of hypo, forms a double salt, which is practically insoluble in water, though it is freely soluble in a large excess of hyposulphite of soda. Now, it is very obvious that, if this large excess is not present, the whole of the double salt is not brought into the soluble condition, and therefore no amount of washing will remove it. The hyposulphite of soda may be removed by washing, but not the silver compound that remains in the paper and gelatine to hereafter work mischief, particularly if the pictures are exposed to adverse conditions—moisture, prolonged exposure to light, &c., as witness many gelatino-chloride printed-out pictures. If a print is thoroughly fixed, a comparatively short washing will suffice, because the salts in the picture are in a soluble condition; but, unless they are so, it is practically impossible to eliminate them with any reasonable amount of washing.

We shall probably, at an early date, recur to this subject and give some practical hints upon it, for we say unhesitatingly that, when worked with due precautions, the gelatino-bromide process is one of the most, if not *the* most, permanent of all silver processes.

**Lightning Photographs.**—Some attention has lately been given to this subject, and, in the columns of *Nature*, have been published letters from Lord Kelvin, and Dr. W. J. L. Lockyer referring to personal experiences in connexion with a non-photographic phenomenon which apparently has its exact analogue in published lightning photographs—the appearance of “black flashes.” These observers, however, explained the cause of the presence of their flashes as being entirely subjective; fatigue images on the retina of flashes seen immediately before, and hence visible as dark objects whenever the gaze, within a second or two of time, was directed to a lightning-illuminated picture of the sky, the eye remaining stationary for a moment. The explanation is, of course, correct for the occasions referred to; but it cannot by any means be allowed to stand as a sufficient explanation for all cases, for the very simple reason that photographs have been, from time to time, taken in which dark flashes have been perfectly visible.

MUCH speculation has been caused by the phenomenon; many theories advanced in explanation. Last week in *Nature* there appeared an article illustrated by a process illustration from a photograph taken by Mr. W. Aikenhead in Tasmania, and here we have not only one but several representations of black flashes. The picture was taken about nine in the evening, just at the height of the storm, with a hand camera, and is further noticeable from the fact that the flash portrayed is seen to be a triple one, three flashes almost blended into one, forming a kind of ribbon. This forms an excellent

example of a photograph of a much-disputed type. As most of the negatives of this character have been taken with hand cameras, it has been customary to dismiss the question by the simple assertion that the camera has moved during the photographing, and, as a flash often occupies an appreciable length of time, the movement has caused the image to travel and so the streak looks broad. This, no doubt, will explain many such pictures; but there are other photographs in which such an explanation would be untenable. It frequently happens that several flashes in immediate succession, and over the same path, occur. A photograph of such a condition was published in the journal we are referring to in October 13, last year; flashes had followed indelibly the same path at the estimated rate of thirty to thirty-five per second. Several eminent men discussed this appearance with non-accordant conclusions.

It is thus evident that there is plenty of scope for further photographs of these subjects, and those of our readers who take an interest in the subject cannot do better than have hand cameras ready-charged, as recently suggested by us. In the article referred to there is, however, strangely enough, a reference to a letter sent to the Royal Society by a writer in Buluwayo, who describes a flash that remained visible for sufficient time for the observer to call his friends out of an inner room to come and look at it, for them also to see it. “There could be no mistake about it, it was as distinct as possible, and it must have lasted fifteen seconds at least.” Our readers must not from this judge that recent remarks by us on the subject need recasting, for the occurrences we describe are only occasional, and it still remains true, as we said, that the best plan is to place the camera on a stand, with the cap off the lens, during a thunderstorm, and trust to chance that a flash will be included in its field of view.

**A New Mode of Photographing Star Spectra.**—Messrs. E. G. Hall and F. Ellerman have contributed to the *Astro. Physical Journal* an article describing some recent work with the great Yerkes forty-inch telescope in this direction. The telescope was only corrected for the visual rays, and thus the region of the spectrum that could be portrayed was limited, hence it was felt desirable to introduce a correcting lens. This, when made, consisted of two lenses of positive form, which were of 3.2 centimetres in diameter, and were placed not against or forming part of the objective, but in the cone of rays proceeding from it, and at a distance of about thirty centimetres from the slit of the spectrocope. The corrector has the effect of shortening the focus of the telescope by about six centimetres, “but, at the same time, so alters the curve of the original steepness of the colour curve that it is found possible to photograph a much larger extent of spectrum at the same time.”

#### JOTTINGS.

DOCTOR BRIGHTON, as Thackeray affectionately styled the Queen of Watering-places—the sovereignty of the Sussex watering-place, by the way, is disputed by several other British coast resorts—Brighton, be she Queen or Doctor, boasts possession not only of a considerable number of photographers, but also of many who, by reason of the excellence of their work, are entitled to rank as first-rate men in their profession. In the less aristocratic quarters of the town the badly printed and crudely vignettied surface print still holds great sway; but, if the attention be directed to those brilliant thoroughfares which compare not unfavourably with the principal “shopping” streets of the West-end of London, it will be seen that a very handsome set of photographic establishments, exhibiting capital work, is a prominent feature of London's largest suburb. This, at any rate, was the impression made on my mind one afternoon last week, when the interval between a couple of business appointments gave me the opportunity of a ramble round the town, which I utilised by studying local photography. Something like the omnibus-driver who, having a day's holiday, devoted it to 'bus riding with a friend.

There have been, and are, some familiar names associated with Brighton photography. Was not Mr. J. J. E. Mayall thrice Mayor of the town? As long as I can go back in photography there has been a Fry at Brighton. At present the name survives in the person of Mr. A. H. Fry, whose studio is at East-street. Mr. Fry not only makes charming medallion and other portraits, but takes capital views. It transported me, in fancy, right away back to the early eighties to see at East-street a very fine enlarged portrait of the late Mr. Clarence Fry, whom I used to meet at the great Baker-street house, in London, and who was one of the most lovable personalities of his time in photography. Mr. A. H. Fry, as I have hinted, is *facile princeps* at both portraiture and landscape, and his elegant establishment is within a pebble's throw of the King's-road.

Yet another familiar name catches the eye—that of Lombardi, in West-street, the busy thoroughfare which the tripper traverses from the station to the sea. The present proprietor of the business caters for the popular taste by supplying bromide midget portraits at a low price. For work of this kind there is always a strong demand amongst the masses. While looking at a well-executed enlargement placed on view, the subject being a part of the beach near the Grand Hotel, I was amused at overhearing the exclamations of delighted surprise with which a group of persons recognised some figures of children paddling in the water. I know none amongst life's little pleasures which is so keen as witnessing the momentary wonder of those who suddenly recognise themselves, or somebody they know, in a photograph which they have never before seen. Other popular photographic names in Brighton are those of Mora, A. & G. Taylor, and the total number of professional establishments there is between thirty and forty.

Pictorial portraiture in its highest developments, as they are manifested at the principal exhibitions, is apparently as slow to make its appearance at Brighton as elsewhere—there are no Crookes, Barnetts, or Hollyers in the town—nevertheless, with this reservation, you see there portrait photography of exceedingly great refinement and skill of execution. At the establishment of Messrs. Mayall & Newman, who are fighting the Brighton Corporation over structural alterations which, when completed, will give them a fine frontage to the King's-road, I see, in addition to a much-admired presentment of the great tenor, Edward Lloyd, a speaking likeness of a certain eminent optician, who shall be nameless. As a cricket lover, too, I find time to scrutinise some of Messrs. Hawkins' series of famous batsmen, bowlers, and fielders. For many years past Messrs. Hawkins have laid themselves out to work with the camera in the cricket field, and innumerable photographs of the kind have come out of Brighton to enlighten adherents of the national game as to how their heroes of ball or willow comport themselves in action.

In the Western-road the name of Henry Spink (who has a tastefully decorated studio, &c.) reminds me that it has for some time been absent from the exhibitions, at which he justly gained notice for his portraits of little children. Apparently it is to this branch of photography that Mr. Spink devotes himself, for he shows a great deal of it which is full of the qualities of charm and naturalness. The same pleasant thoroughfare includes the old photographic name of Edmund Wheeler, whose portrait work, especially that of lady sitters, is most admirable. Most of the photographers I have named show their prints in sepia platinum, or carbon, which struck me as being in pronounced favour. Don't imagine that the medallion portraits, to which I have referred in a previous paragraph, are tiny little pictures. They are from two to three inches in diameter, are quite circular, and, printed to a sepia tone on square brown cards, make very effective little photographs.

It would be a curious taste on the part of the public which could not gratify its predilections in photographic portraiture at Brighton, where, as I have briefly tried to show, all grades of society, from the highest to the lowest, are catered for. Broadly speaking,

Brighton photography is quite as good as you obtain in London. The same thing can be said of Edinburgh, Glasgow, and other large towns as compared with the metropolis. Yet the public perceive, or affect to perceive, a difference unfavourable to provincial work, as it is one of the commonest things for people to decline to be photographed in a large provincial town, on the grounds that they would be done "better" in London. If they *do* submit to being provincially photographed, it is only with the idea of tentativeness—London, London must ultimately have the honour of transferring their lineaments to glass and paper. If the destruction of this delusion, so characteristic of the great and unthinking British public, took away some business from London, it would only mean a proper adjustment of the balance between town and country; for, as I have said, you get quite as good photography out of London as in it.

But, to return to Brighton: not only are those who want to be photographed well provided with suitable opportunities, but the equally large class who take photographs for amusement can easily minister to their requirements at the well-known and up-to-date photographic-dealing establishments of Messrs. Churchill, East-street, and Messrs. Hardcastle, East-street, both of whom supply the latest goods on the market. London-by-the-Sea is always animated. Fashion annexes it in the winter and spring, and leaves it to the tripper in summer, so that life of many kinds is ever to be seen there, and an invigorating air remains with it all the year round. In what happier circumstances could professional or amateur photography be practised with an hour's journey from London?

COSMOS

#### NOTE ON CLOUDS: THEIR USE AND ABUSE.

It is at present the custom with a good many workers to put clouds into all the landscape work they do. This appears to me to have its faults. For instance, one is often greatly impressed with a subject where the sky is absolutely blue, without a cloud in it; therefore it strikes me that to introduce clouds into a picture of this description is, to a great extent, interfering with nature, and with the effect that the whole character is altered, and what one desired to express in monotone is, more or less, marred in consequence. There are, of course, many instances where the introduction of clouds is a great gain, but I specially refer to nature in its peaceful form, when the very grandeur of the scene is chiefly due to nature's silence, and one can almost imagine that the world itself was indeed asleep, so still is everything around one. It is in such a case as this that the introduction of clouds is, to my mind, a marring element. Granted that one has taken a woodland scene, glade, or, indeed, almost any view under the conditions above described, then, in after-treatment, I think the judicious sunning down of the sky adds not only to the pictorial quality of the picture, but lends value, if not grandeur, to the subject.

There is, of course, the other aspect under "The Abuse of Clouds," which I will only briefly touch upon. It has struck me how often, when the insertion of clouds by double printing has been resorted to, the clouds selected were at distinct variance with the character of the subject chosen, and, instead of strengthening the picture, had directly the opposite effect, tending more to irritate than to please.

W. I. CHORALL.

FOCussING HARVEST SUBJECTS.—Having selected and arranged our subject, leaving out as many things as we find we can do without, the next question is focussing on the ground glass. Now, here comes in taste and judgment. Let us consider this question. Why do we focus a part or the whole of a picture sharply? The answer is, We want to see clearly and distinctly, and a part or the whole of the subject. Now, in the subject before us, what do we want to see? First, we want to see the men, and then we want to see their immediate surroundings; the distant fields we know are there, but they only interest us in a general way. Well, then, we shall just give attention to the figures. We also want to see a few stalks of the corn; first, those that are close to the men, but we do not want to see every single stalk or ear. If we see two or three, the others we can take for granted. Therefore, in this case, we shall give our chief attention to the men and their immediate surroundings, and then use a small enough stop just to give us the general impression rather than the microscopic detail of the rest of the picture. —*Photographic Scraps.*

## FINISHING BROMIDE PRINTS.

SINCE the advent of the air brush, most of the large photographers have used it for "working up" their bromide prints and enlargements; but the price of it is prohibitive to many who have but few prints to finish. They are either content to send them to a trade enlarger to finish, or leave them as they are. It would surprise most photographers what an improvement can be effected in the finish of a bromide by the judicious use of the most simple and inexpensive tools.

The surface of bromide prints lends itself admirably for "working up" on account of its rough surface. By "working up" is meant generally improving, removing defects, strengthening faint detail, brightening flat high lights, defining outlines, drawing in backgrounds, &c.

Contact prints require but little treatment unless they are flat, as the greater part of the detail can successfully be brought out in the development. With enlargements it is different, their outlines will not be so sharp and well defined, and they will have lost a little in brilliance, so they will require more working up to remedy these defects. The articles required are, one bottle of black stumping chalk, a tablet of Indian ink, one tube of Chinese white (moist water-colour), a bundle of paper stumps, two fine camel's-hair brushes, and one Hardtmuth's black chalk crayon, No. 5.

All the above may be bought at any artists' colourman for less than two shillings. A palette for the colours and a pad for the powder will also be required, but these need not be bought, as excellent ones can be made at home with very little trouble. Two clean waste negative glasses—one for the Indian ink and the other for the Chinese white—will do for palettes. To make the pad, obtain an empty tobacco tin (or other tin about the same size) and a pyro bottle cork; cover the latter over with cotton-wool to make a nice smooth pad, and over it stretch a piece of clean chamois leather, and stitch tightly together at the bottom, so as to leave no creases on the top part. Place in the tin, smooth side up, and fill in the sides with paper.

To prepare the pad for use empty a little of the black chalk (very little) on to it, and evenly rub all over with another piece of chamois leather. The chalk should be just sufficient to black the pad all over without leaving any loose on the surface. Too little chalk can easily be remedied, but not so too much. An easel will be of great assistance, but is not absolutely necessary. An excellent substitute can be made by placing a box on the table in such a position that the photograph is tilted at an angle of about forty-five degrees. The print must first of all be mounted, as any attempt to mount it after the "working up" would only spoil it. It will be advisable to practise on spoilt bromides at first, they make excellent trainers on account of their defects. A mask large enough to cover the whole of the mount, back and front, only leaving the print showing, must be cut out of paper. This will prevent the mount becoming soiled by any loose particles of chalk. The high lights are the first parts to touch up, which are done by means of the Chinese white, a little of which should be squeezed out on to one of the glasses, and some water added and well mixed. The finest brush may then be taken, and lightly dipped in the fluid, taking care not to have it too full or too dry. It should be applied to strengthen the brightest high lights of the photograph, such as that on drapery, the glitter on water, the whites and shine of the eyes. Care must be taken not to make them too white or to destroy any half-tones. If the picture is rather flat, it will not stand the high lights being made white, so a little of the Indian ink (very little) may be added to make it to a slight greyish-white. It is well to test the colours and chalk before using on a piece of waste bromide paper of the same surface as that used.

The backgrounds of vignettéd portraits may often be improved by painting on a wavy wash of white and grey, taking care not to have it too uniform. Clouds may be painted in on a landscape sky by means of washes of white for the bright portions and graduated greys for the shadows. For the first attempt it will be best to copy some clouds from a photograph or engraving. It must be remembered that the clouds must be lighted from the same side as the view, or the result will be unnatural. For instance, if the light comes from the left, the clouds must have their brightest part that side, and the shadows the other. Before attempting to use any of the chalks, the print must be allowed to thoroughly dry, or it will smudge. Sharpen the black crayon up to a fine point by rubbing on sand paper, and finish off on emery cloth. Then wipe on a piece of linen to remove all superfluous chalk, and it will be ready for use. When in use, it must be held between the thumb and first two fingers, about two inches from the point.

It must be held very lightly, so much so, that it practically rests on the hand. Although held lightly, it must be capable of making a firm, fine line, without any shakiness. It should be held almost upright in making a fine line, but, where a thicker one is required, it may be obtained by lowering the angle so that it is made by the side of the point. For a faint line the crayon is held lightly, and, for a deeper, firmer. The use of this crayon is to gently draw round the outlines of the different objects and make them more definite. Faint detail may also be made clearer by its judicious use.

It can be used to work up the shadows of the hair and eyebrows and the pupils of the eyes.

Now for the use of the chalk and stumps, which is the most important part. They are used for deepening the shadows, working on the half-

tones, and toning down too pasty high lights. The method of using is to hold the paper stumps about half an inch from the end by the thumb and first finger, using the second finger underneath as a rest. Draw the point part over the pad, so that about half an inch of it is covered, and then test it on a piece of waste bromide paper, to see that it is not loaded with too much chalk. A beginner usually makes the mistake of using the chalk too thickly. The shadows must first be worked over, taking care not to destroy any half-tones which connect them with the high lights. The stump ought to be held in such a position that the point is not used, but the side of the point. If the stump is about three inches long, this will mean that the end will be about one inch above the picture. It must be held lightly and worked from left to right with a gentle rubbing motion. It should on no account be scraped along. If the shadows are not deep enough, the stump can be recharged with chalk; and, if the shadows have been made too deep, the only plan is to remove some of it by gently rubbing with clean cotton-wool. Do not sponge or use water, or the result will be failure. The half-tones may then be improved. For these the stump will require but little chalk, and it must be so worked that they graduate into the shadows and high lights. Numerous other improvements can be effected in bromides by the judicious use of the above simple implements, and will require but little practice to become proficient in their use.

OSBORN THORNBERRY.

## THE SOUTH LONDON SOCIETY'S THIRD CONTINENTAL EXCURSION.

## A WELCOME FROM THE BELGIAN ASSOCIATION OF PHOTOGRAPHY.

UNDER the combined leadership of Messrs. William F. Slater and Walter D. Welford a party of thirty-eight members and friends (four ladies) have just spent a very enjoyable week in Belgium. Leaving Liverpool-street on Saturday night, August 19, *via* Harwich, it was found, as soon as the members were safely housed in the reserved berths, that only Mr. Welch, of Portsmouth was missing. Although the boat was very crowded, the arrangements made beforehand ensured comfortable accommodation for each member of the party. As soon as the boat was well out to sea, the evening being pleasantly cool and the sea calm, an endeavour was made in the smoke-room to introduce the visitors and members to each other. One or two gentlemen make a good start by walking the deck all night, but the majority sooner or later found their way downstairs for sleep.

Sunday morning proved fine, and, as it was known that the journey up the Scheldt afforded good opportunities for the hand camera, most of the members were on deck pretty early, and thus early in the trip plates were exposed, some fine cloud studies and passing vessels, and one or two villages on the banks, being secured in passing. Antwerp was reached about ten, and a start was made for the East Station to deposit the luggage. Owing, however, to the enormous crowds pouring in from the country to see the great religious procession, and the later one in honour of Van Dyck, it took some time getting to the station. After a slight lunch every one proceeded to view the Van Dyck procession, and naturally got very much separated. Some excellent shots were obtained, the wide boulevards and orderly people affording much assistance; indeed, one energetic lady member induced some of the huge figures, camels, &c., to stop and pose for her. Leaving Antwerp at 2.50, the Hôtel du Rhin, the headquarters at Brussels, was reached about four p.m. This hotel was chosen on account of its proximity to the Gare du Nord, the station from which all the excursions started save one. It took the leaders some time to allot the bedrooms to suit the married couples and friends who wanted to be together, and at six o'clock everybody was ready for dinner. Later on, small parties visited the Fair, the Palais d'Été, a variety entertainment, and had a good general look round the main boulevards and streets, which, being Sunday night, were well thronged with gaily dressed people.

*Monday.*—The leaders had to leave breakfast early, in order to interview the station-master about the arrangements for the various excursions. Single fares for the double journey were granted, the party to be at the station fifteen minutes before the departure time of the train. Two corridor carriages were reserved on the 9.15 a.m. train to Ghent, which, with only one stoppage at Alost, was reached 10.34. The members set to work in earnest immediately, many patronising the Cathedral of St. Bavon, permission for a limited time being readily obtained. It has an unpromising exterior, but inside it is one of the most richly decorated churches in Belgium. The rest of the members went on further and gradually divided into twos and threes. The canals, the old castle of the Counts of Flanders, the Palais de Justice, some quaint courts on one side of a canal, the Hôtel-de-Ville, the Church of St. Jacques, and many other subjects kept every one busy. Upon arrival at the station, considerable excitement, huge wreaths, bands and banners told of something special. It appeared that on the previous day, at Antwerp, a Ghent musical society had gained an important prize, and this was a huge reception awaiting their return. Leaving Ghent at a few minutes before seven, headquarters were reached in good time for dinner, 8.30 p.m.

*Tuesday* was an early rising morning, breakfast being at 7.30 a.m. The train journey to Namur, in reserved corridor carriages, was enjoy-

able, and the party arrived just before eleven o'clock. It had been intended to take the boat down the Meuse to Dinant, but, as it leaves Namur at 8.45 a.m., necessitating a train at 6.48 a.m. from Brussels, the idea had to be given up, especially as it would be after midnight when headquarters were reached. A walk along the river, where Mr. Welford took his first biokam film of the party walking in procession, was followed by lunch, and the intermediate time before the train started was utilised in visiting the Citadel, &c. A short train journey brought the party to the picturesque town of Dinant. Here the members had hardly got out of the station before commencing work. Dinant is attractively situated at the base of high limestone cliffs, and even general views of the town are worth photographing. At the highest point of the cliffs is situated a fortress, a conspicuous addition to the landscape. Many members negotiated the 400 odd stone steps to the summit, from which excellent views of the valley were secured; but most of them had a rest at a little café upon their return. Dinant is a charming place for photographer and tourist alike. The train was again taken at 6.40 p.m. to Namur, where dinner had been arranged for, and eventually the party reached Brussels some little time after midnight, all pretty tired, but satisfied with the enjoyable outing.

*Wednesday.*—A short excursion was taken, owing to the long day before, and Waterloo was visited. Taking the train at 9.45 a.m., Braine l'Alleud was reached at 10.40. The Lion Mound, Hougomont, the various monuments, &c., were all visited. On the way to the Mound another animated photograph was taken in the biokam. The members arrived home at varying times in small parties. After dinner, a start was made for the Waux Hall musical gardens, for which the Association Belge de Photographie had sent the tickets. The gardens were filled with a select audience of some hundreds, and the orchestra was a magnificent one. The party was welcomed by MM. Rutot (President) and E. Stadeler (Secretary of the Brussels section), M. Vanderkindere (General Secretary of the Association), and other members, Madame Rutot entertaining the lady members. Soon after arrival, the orchestra played "God Save the Queen," to which Mr. Welford initiated in reply to the honour three good British South London cheers. It being a public-garden entertainment, the meeting was quite informal, but the party fully appreciated the honour and endeavoured to be paid them. The friendly feeling shown by this gathering of Belgian and English photographers made Wednesday a red-letter day in the annals of the excursion, and the wish was freely expressed that the South London Society might have the opportunity of reciprocating the attention paid them in Brussels.

*Thursday.*—Leaving Brussels at 9.30, and arriving at Antwerp at 10.44 a.m., the day was devoted to that paradise for photographers, whether hand or stand workers. Mr. Slater was most assiduous on behalf of those desirous of photographing inside the Cathedral, a franc each admitting any member whilst the building was closed to the general public. Others went to the quay, and roamed about the old streets, the docks, and various quaint courts they discovered. In the afternoon several patronised the Zoo, where no restrictions as to the use of cameras exist. In fact, every one had been somewhere and found "a real gem," and the train journey home was a friendly bragging match as to the respective picturesque finds. Dinner at eight o'clock, with a stroll afterwards, concluded a most enjoyable day.

*Friday.*—According to arrangements made on Wednesday night with the Belgian Association, MM. Rutot, Stadeler, Delevoy, Vanderkindere, and Nonpere called at the hotel at ten o'clock to take the party round about Brussels. Mr. Slater, however, was anxious to secure a group of the whole party and their Belgian friends. This was accomplished in the Botanical Gardens, and then followed a delightful and varied trip, commencing with the canal, fish market, flower market, then up to the Bourse, the Maniken, a short rest was taken in the Petit Sablon Gardens. Then the tram was taken past the Palace de Justice to the Bois de la Cambre, the great park of Brussels, where lunch was partaken of, and a rustic bridge much photographed. Another tram was then taken to the Parc du Cinquantenaire, in which remain several buildings of the great 1897 Brussels Exhibition. Here the Panorama of Cairo was visited, and a few shots were made at it. The electric tram was then taken to Tervueren, and a really pretty journey through part of the Forêt de Soignes brought the party to a very large and beautiful park, containing a fine château and lake. It is a Royal park, but the château is now used as a museum. Amongst the trees some of the stand-camera men were very busy, and as a good deal of ground had been covered during the day, rendering it difficult to find time to erect the tripod, they made up for lost time. The return journey by tram was just as pleasant, and the party reached the hotel at seven p.m., well satisfied with the efforts of the Belgian friends to provide an interesting day.

After dinner a little surprise, planned by Mr. Mason, of Fakenham, Mr. Rogers, of Croydon, and others, took the form of a presentation to Mr. Slater. Mr. Newson, in a neat little speech, referred to the untiring efforts of that gentleman for the comfort and enjoyment of the party, and that it was a unanimous wish that they should recognise his labours on their behalf. He accordingly had the pleasure of handing to Mr. Slater, on behalf of the ladies and gentlemen of the party, a slight token of their esteem. This took the shape of a handsome card basket

in oxidised silver. Mr. Newson continued that they wished also to recognise the services of their other leader, Mr. Welford, but, fortunately for him, he had brought Mrs. Welford with him, and following the precedent of last year, when Mrs. Slater was similarly honoured, he had the pleasure to hand her also a token of their appreciation. A very pretty silver sugar basin was then presented to her. Mr. Slater and Mr. Welford (the latter evidently much taken by surprise), having replied, Mrs. Welford was induced to say a few words, and a pleasant little function brought the dinner to a close.

Saturday was devoted to shopping, buying presents for wives and relations, and in cigar and tobacco purchases. Several members took out their cameras for subjects left over to the last, and with lunch at one o'clock there was not much done but packing. Leaving at six o'clock, the boat was reached in good time, and the party settled down for the last bit of the excursion, the voyage to Harwich. In the smoke-room Mr. Slater got all the accounts in order, and, to every one's satisfaction, it was found that the total cost was about 5s. per person less than the advertised estimated total. More speeches followed, three visitors gave in their names for membership of the Society, several medals were offered for competitions in connexion with the trip, and things were kept going until a late hour. Even after this a little excitement was caused by the temporary grounding of the boat upon a sand bank, and a very narrow subsequent escape from a collision. But the South London are a hard lot to kill, and so Harwich was reached in good time, the Customs passed, and the train steamed into Liverpool-street punctually on schedule time.

The whole trip was a great success; not a drop of rain fell, the leaders worked well for the party, there were ample subjects for the innumerable plates taken (over 2500 exposures, an average of about seventy to eighty each photographer), the kindness of the Belgian Association and the general amiability and sociability of the members and friends all worked to make the third Continental excursion of the South London Society a record in pleasure as it was in number.

#### THE REPEATED USE OF DEVELOPING SOLUTION.

At the London and Provincial Photographic Association, on August 31, a long discussion took place upon a point introduced by Mr. R. P. Drage regarding the repeated use of a developing solution. Many there are who claim that they can use their solutions time after time without appreciable difference in the result, whilst others maintain that the results are not the same with a developer used more than once. One man who was asked what reason he had for preferring to use a developer a second time answered that he could use the water he washed with more than once, but still he did not, and it had been said that it was really false economy to use a solution for more than one plate. Mr. Drage thought, however, that photographers often used their developers repeatedly up to three or four times, eikonogen, hydroquinone, amidol, and some of the other developers allowing of this without producing marked difference in the results.

Mr. J. S. Teape said he was in the habit of keeping his old developing solutions, which, in the case of a little over-exposure, he found it well to employ in preference to the freshly made solution. He had only availed himself of this fact during the past few weeks, hydroquinone, rodinal, and amidol alike answering the purpose. The activity of the solution was a trifle slowed down, possibly due to the presence of a small quantity of bromine liberated from the plates before developed, which retards the action to some extent.

Mr. E. J. Wall said that the only difference between the fresh and the old solution was that the latter was slower. The resulting negative, he considered, would be the same in any case, except that it would require longer to come to the state desired with the used solution. He expected that a fresh developer, with the bromide increased to correspond with the old developer, would act identically with this latter solution.

Mr. Teape said that, if one slowed the developer to a small extent, one increased the contrast proportionately in the result, and this held, he thought, with any developer to be named. A developer which had been allowed to stand and absorb oxygen, or one in which the bromide had been increased, certainly gave greater contrast.

Mr. H. C. Rapson thought it was a fact that more detail was obtained in the shadows of a negative by diluting the solution.

Mr. Teape pointed out that he did not include the means of slowing development by dilution, but where the reducing agent was kept at normal strength and the slowing effected by other means. Then the contrast would be increased, but dilution would give the detail. He also pointed out that under-exposures which, with twenty minutes' development, would result in a black-and-white negative, might, by modifying the solution so as to extend the time for completion to three hours, be made to yield a negative with good detail in the shadows, and be quite printable. But many people thought twenty minutes a very long time, and three hours out of the question.

Mr. W. D. Welford asserted that a developing solution could be used again and again with good results. Two ounces of developer, developing two plates at a time, might be made to last out for twelve plates, show-

ing that it could be used six times at least. The effect was to slow the development, but the result was much the same. He had been using ortol, which showed a continuing power much more marked than anything he had seen. If, for instance, one wished to get a little extra density upon a plate with this developer, it might be taken out and washed under the tap. He had even gone as far as to put a plate, as soon as the image showed, into a vessel of plain water, or under the tap, and by this means completed the development. Thus it was not wise to trust to water to arrest development. The fixing solution alone would suffice. He was now working first with an old solution of ortol and as fresh developer, plain water restrained and plain water. With these one could negotiate any kind of exposure.

Mr. Wall said there was admittedly an enormous excess of reducing agent in every formula, most of which was wasted, and it was certainly possible to use repeatedly the same solutions without risking a weakening of its action, but simply slowing it. The result was the same practically, if sufficient time were allowed.

Mr. Teape could not agree that the result was actually the same. In a batch of ten plates, one he found it impossible to develop, even after forty-five minutes' treatment; but, transferred to a fresh developer of the actual constitution of the used developer, the image came up wonderfully.

Mr. Rapson said he had used a plate with which no bromide was allowed in the formula, and its action was to slow the action at least four times. He noticed that with the developer advised a plate would be completed in from four to eight minutes in the fresh solution; but, if a second plate were put in, five minutes showed no action.

Mr. Welford undertook that a bottle of old ortol developer, bottled for three months, would develop a correctly exposed plate quite satisfactorily.

Mr. Wall stated, finally, that it was true that, for five or six times, any normal developer would work well under repeated use. It was then not false economy at all. He would exclude pyro formulae, perhaps, because of its strong staining properties, which would in themselves preclude its use.

### THE ILLEGITIMATE IN PHOTOGRAPHY.

[Abstract of paper read at the American Convention.]

We meet for improvement, and to improve we must observe the work of others, as the work displayed is, or should be, their best effort; and when we have the best efforts to study there is always something to learn. In speaking of best efforts I come to one class of the illegitimate, and that is the so-called freak or accident. If we are gathered here to reward careful, painstaking, conscientious work, how can we consistently reward the result of an accident or failure? And that is just what has been done on some occasions. In one instance the party receiving a reward or prize said he had thrown the negative away, being so much under-timed as to render it utterly worthless. Seeing certain effects in a painting, he had one day brought it from the waste box, and, making a print, which, of course, was flat, weak, and grey, called it *Winter Twilight*, or some such name, although the exposure was made in mid-day. Now, was it improper to award a prize to that picture? Some might say the man deserved it for taking advantage of the effect to produce his picture. Others would say, "What is the use of our trying to improve in our work by careful study when a failure gets the prize over our honest efforts?" We surely cannot improve by having a failure held up to us as the standard of excellence. Under this condition the work was not legitimate.

Now, in another connexion, I might mention the etching or other work done on negatives, by which effects are sought after that cannot be produced by pure photography, such as the introducing afterward of water, rocks, trees, and various other effects. In most instances it would have been better left undone. Whether done well or not, it has no place in photographic competition, as a draughtsman or an artist is one thing, and a photographer another. Such work might be entered in a class of its own, but should not be placed in competition with pure photography. As a man may be thoroughly artistic in photography, and, unless it is a special gift, may not be able to draw an object, no matter how many pictures of this kind he studies, therefore, at a convention of photographers, pictures containing other than that which can be produced by photography pure and simple should be considered illegitimate. Our intention should be, after seeing the best that can be produced with camera and plate, to try and equal it. The camera and plate are to be had. All they need are brains and study at the back of them. It is the study of a lifetime to pose easily, light properly, and get on your plate what you are after, without taking the time to look around for accidents or learning to draw.

Sometimes I have heard the word "illegitimate" applied to certain odd effects in lighting and printing; but, if they are the results aimed at and produced by means within photography, I should not consider them illegitimate, though often not in good taste.

Photography is no longer in a primitive state. The time when chemical results alone were the greatest virtues to be sought for is past. We now have our plates given to us in uniform quality, with the necessary formulae to obtain the best results. Then, why consider

chemical results as the greatest point in awarding prizes? There has been such great progress made in a true art way that we should now look to the art quality as the greatest factor of merit in modern picture-making. It will be safe to say that a man acquainted with the necessary art principles, and starting out to make his picture based on this knowledge, will not stop at having his composition and lighting correct, but will look to his chemical work to properly render the effect he wished to produce. Therefore, recognising one, we may recognise the other.

Another point that should be considered in this advanced period is originality or individuality. To destroy this would be the greatest wrong. We should also always put as much of ourselves in our pictures as is possible, adhering still to the art principles involved. And I will repeat that any effect, no matter how odd, if it was one sought for knowingly, and was obtained by a purely photographic method, will have to be classed as legitimate.

However, I do not believe in encouraging absurdities under the guise of art. I sometimes feel that a good many of us trust, in a blind way, to the word "art" to excuse us in making any kind of freak. By the word "freak" in this instance I mean any effect produced outside of the limits of good sense and good taste.

J. S. SCHNEIDER.

### PRICES AND HOW TO GET THEM.

[Abstract of paper read at the American Convention.]

Price depends entirely on place, circumstances, experience, and merit, as in all other occupations or professions. Surely the newly graduated practitioner of law or medicine would not expect the same fee as the experienced expert of a quarter of a century. In a manufacturing town, in which the inhabitants or a large majority were in receipt of a bare living income, they would not pay the same prices for photographs of even the first quality as in cities where there might be many wealthy people. Here, certainly, the principle of the nimble sixpence must prevail, and larger sales with small profits be the rule. Then, again, comes the question of expenses. I find many photographers in the smaller towns much more prosperous in proportion to the amount of business done than those in large cities. In the latter the expenses often are prohibitory to the attainment of a profitable result. If I make my lowest-priced photographs at \$6 per dozen, and some of my friends from the smaller towns get only \$3 for the same quality and quantity, they should be consoled with the thought of difference in expenses. Many of this audience do not pay as many hundreds of dollars for rent as we pay thousands. How would you like to meet a disbursement of \$4000 a year for rental only? Then we have six months of paying business, while most of you have but a slight falling off in the summer and mid-winter months. Then, again, as I have intimated, is the matter of skill and experience. Possibly my forty years under a skylight, with repeated visits to Europe, studying in the great foreign schools of art, entitle me to a larger compensation than the tyro in the art.

These suggestions are all general, and are apart from special circumstance, such as the competition of the peripatetic or wandering photographer, who attempts to "skin a town," as the saying is, by moving in, reducing prices, and, when the sensation of his coming has subsided, moving out. Such occurrences can only be met by keeping up with the art, making such excellent work that our patrons will not be tempted to leave us. The public is not such a fool as we are apt to consider it, and there is in almost every town a spirit of loyalty towards the deserving in all kinds of business.

The roving photographer doesn't come to conventions. You have the advantages that this Association extends to its members by seeing the best work done on earth, receiving instruction in the practical or mechanical processes, and being educated on the art side by the distinguished men who have addressed you in the various schools and lectures. The man equipped as he will be here is in no danger from unprincipled competition. Strong men don't resort to it, and strong men are always in demand in all kinds of business.

I started, as a basis, with the lowest-priced picture, at \$6 a dozen for albumen prints. I discovered, after a while, that I was making a very few, and I supposed that the average price of pictures was more than the price announced. Of course, this was the result I intended to accomplish. I did it in this way: When a patron inquired the price of pictures, I, or my clerk, always answered the patron promptly, when asked "How much are your pictures?" by responding, "\$6 for this style, which is the general style in use." We never attempted at the start to get them away from that, nor did we endeavour, by showing them a round-cornered card, and pretending or claiming that upon such a card a more expensive result was produced, and upon that claim charging them 50 cents or \$1 more. If desired, we showed them a better style, such as platinum and matt picture, the price being \$6 for albumen pictures, \$8 for matt pictures, \$12 for platinum, and \$15 to \$18 for carbons.

Last winter I was curious to find out what the average price was which we secured from every man who came into my front door with the intention of purchasing or ordering a dozen cabinet pictures ostensibly at \$6 a dozen. I took the average for twenty-four working days. At the end of that time I found that the average price for my pictures had been

\$11.34 a dozen. I mention this to encourage you in showing to the public a very high standard of work.

The public is most sensitive upon their personal appearance, more sensitive upon that point than any other that rules human nature. You may find an old man or an old lady coming in who has not looked into a looking-glass in ten years, any more than just to give a little touch to the hair; but that man or woman, when approached upon the side of their personality, or their personal appearance, when you get them under the skylight—I am sure we have all had the experience—that man or woman will fix and prink a great deal more than young people. I mention that to illustrate the fact of this peculiar sensitiveness of human nature with which we deal, this vanity of personal appearance. So that, if you present to them a high grade of artistic excellence in your work, they will make sacrifices to possess such a picture as a personal gratification; not only a gratification to themselves, but a matter of pride in behalf of their family. An incident comes to my mind at this moment: A lady came in with her child and said, "Mr. Rockwood, I can hardly pay you \$6 for my little girl's picture, but" (looking at the platinum pictures), she added, "I must have one of these pictures if I have to cut off some of my household expenses." I was rather sorry to have her make such a sacrifice, and, being a personal acquaintance, I made a concession in price for her. But that illustrates the fact that they do want the very best.

And now, if I could run up to \$11.34 on an average on pictures, you see what is possible in the way of tempting the public. There was no mistake about these figures; that average did not include a single copy, it did not include a single enlargement, or the increase of an order outside of cabinet-size pictures. While there were a great many that were tempted into life sizes, enlargements, &c., not one single case was there where such were counted in. In addition to that, there was a large number of Salvation Army people, during that month, whose pictures I made for \$3 per dozen. I am a great admirer of that grand woman, Mrs. Ballington Booth. She is a very dear and close friend of mine, and for her sake, and those people who are with her, I made this concession in price at that time, which was a good while ago. During that month there seemed to be more of these Salvation Army people come into our gallery than we had had in a great while; but notwithstanding that fact, the increase was just what I have stated to you.

So, in the art, we cannot as a body fix upon a single, specific agreed rate by which all shall be guided in their prices. It is a question of location, a question of the character of your *clientèle*, and a question of artistic excellence.

There are not too many photographers. If I had a dozen sons to-day, and I found that they possessed at all the artistic element, I would do all I could to bring them into this wonderful art of ours, that is, if they had the enthusiastic temperament required for it.

G. G. ROCKWOOD.

#### SOLUTION FOR MOUNTING PRINTS, &c., WITHOUT COCKLING.

There is a formula in the ALMANAC under the above heading, which several of my friends have tried and failed to get to work, and from the Correspondence column the Editor seems to have had other evidence of failure.

With the use of gelatine for the purpose I have had much experience, and on looking up the formula can at once see where the failure comes in, in fact this is one of many cases where formula—*qua formula*—is of little use unless accompanied with further particulars.

The formula gives Nelson's No. 1 Photo-gelatine. This should not be used, but the cheaper sort, viz., No. 1 sheet, or, in fact, any of the cheaper white sheet gelatines about 1s. 6d. a pound. To make the solution the gelatine should be soaked in the water until it is quite soft, then melted by the aid of heat in a water bath (like glue is always melted); when the gelatine is all dissolved, the spirit must be added in a gentle stream, the gelatine being violently stirred during the addition of the spirit, and care being taken not to add more spirit than the gelatine will take; some samples of gelatine will take more than others, and, if too much be added, the whole will be coagulated and spoilt. When the spirit is all in, add the glycerine and stir them well in.

Thus far the formula, but now for using it. It cannot be used by smearing over the back of the print in the same way as a starch paste, but must be used as follows: Provide two or three sheets of ground glass a little larger than the prints to be mounted, also as many pieces of clean newspaper as prints, the piece of newspaper being also larger than the prints; now with a stiff hog's-hair brush smear over the ground side of one of the pieces of glass, previously dipped in hot water and drained, with the warm mounting solution; do this quickly and evenly, then lay upon it one of the prints face up, take a piece of the newspaper, lay it over the print, and proceed to rub the print down just as if it was being mounted upon the glass, paying particular attention to rub the edges and corners of print; this being done, lift off the newspaper and throw it away, then lift off the print, place it on the mount, and rub it down carefully, especially at edges and corners; for the next print again smear the glass plate and proceed as above. After a few prints have been mounted it is sometimes difficult to get an even coating of gelatine; in this case put that piece of glass on one side, take another,

dip it in hot water, drain it, and start afresh. The gelatine that adheres to the used glass plates can be scraped off and remelted for use again. The jar containing the gelatine should always stand in another jar containing hot water, and, if a large batch has to be mounted, this water should be renewed directly it falls below 100° F., then the mountant will be kept in a workable condition.

This method is an extremely good one for mounting prints upon any kind of mount, and especially thin ones, as it does not cause cockling.

W. T. WILKINSON.

#### THE WORKING HOURS OF ASSISTANTS.

BEFORE dealing with the hours of photographic *employés*, it will be well for me to mark down a few obvious, yet too often forgotten, economic truths. The number of hours an assistant works can be regulated along strictly economic lines, being so adjusted that there shall be no waste of his labour power. Taking the twenty-four hours of a day, we have to deduct a certain number of hours which a worker requires for sleep, rest, meals, &c., the remainder being devoted to his occupation; unlike a machine, a man cannot be kept working continuously, for he becomes tired and exhausted as his exertions are prolonged. There is thus a period when human labour is at its best and most effective, and therefore these hours are the most valuable to an employer, every hour worked beyond this time becoming less productive and, consequently, more expensive. In practice it is found that this loss through exhaustion does not occur during the final hours, but is distributed over the working time of a day of ten, twelve, or fourteen hours; it follows from this that a ten or fourteen-hour day may be of no more value to an employer than one of eight or nine, and that this is actually the case has been proved by showing that a reduction of hours does not mean a corresponding reduction of output. We may say, therefore, that the average wage-earner is capable of only a limited amount of work, which is fully brought out in about eight hours, but may be distributed over ten, twelve, fourteen, or sixteen hours. The general opinion of competent authorities from Alfred the Great downwards has been that eight hours per day is the period during which work is really effective and profitable; the employer who pays for a day of ten, twelve, or sixteen hours is thus buying his labour at the highest, and not the lowest, rate. That this is a fact has been admitted by many large employers of labour, since a reduction of working hours has given them an increased output on working expenses. From the economic standpoint, a reduction of hours may mean a gain to employers when the value of the work done increases; the number of hours worked is no test of the worth of labour, the only measure is the amount of wages into the value of the product, i.e., wages into output, not wages into hours.

Considering the working hours of photographic assistants in relation to the foregoing, we at once observe that they are arranged on the wages into hours idea, and not on the sound principle of wages into output, the whole system being briefly described as "give and take."

The first point to be examined is whether it is better for all concerned to work on the give-and-take plan, namely, the assistant must work late for no extra pay when business is brisk, and may leave early without any reduction in wages when business is slack, or to have a fixed working day throughout the year, with a stated rate of pay per hour, intervals for meals, and all extra time to be counted and paid for as overtime.

The "give-and-take" system is, we know, the general rule in the profession, and, in my experience, has proved a crude, unsatisfactory arrangement for settling a delicate question, being a constant source of irritation between employers and employed, for the reason that it consists of nothing definite and is open to any interpretation. The amount to be given and taken, by whom to be given and taken, and how, when, and where, it is to be given and taken can never be agreed upon, and neither party rests satisfied. An example will show the unbusinesslike character of this agreement; nearly all assistants work extra time during a year at Christmas, or at other busy seasons, and in compensation they receive a Christmas box, a gratuity, payment for a holiday, or some similar recognition of the service. Let us look closer into this custom. In the majority of houses the busy time extends for two, three, or four months at some one period, according to the season, and assistants work several hours daily beyond the recognised time of closing. Putting this at a medium estimate, including earlier starting, shorter meal-time, and overtime, as three per day, or eighteen hours weekly, reckoning the average payment of assistants at 6d. per hour, we have for the week 9s., and for the month 1l. 16s.; or, if we add overtime as time and a half at 9d. an hour, 18s. 6d. per week, 2l. 14s. monthly. For his extra work the assistant may possibly receive 1l. at most in odd half-crowns; the employer is thus a gainer by 1l. 14s. on wages alone, apart from the profit he will receive on the work finished. Multiply the one month's loss by 2, 3, 5, and even 9 and 10, and the assistant's overtime may be valued at any sum from 5l. to 20l. per annum; as a set-off he has the wages paid for dull days and time off, which rarely balances the account. The assistant may not express himself so plainly as I have done, but it is the recognition of the fact which explains his strong objection to unpaid overtime.

It may be urged that fixed hours, a standard rate of wages, and payment for overtime as time and a half could not be applied to photography because of its great dependence on atmospheric conditions and a good supply of strong daylight. This contention had some weight in the days of collodion, but with the advent of gelatine plates of extreme rapidity it may be safely said that, taking the country throughout, there are not more than three days in the year when exposures cannot be made in the studio. Retouchers also are competent to work by artificial light. In regard to printing also, it is becoming more regular with the increasing use of the rapid printing papers, and in a well-arranged printing-room very few days in the year will pass when prints are not obtainable. Altogether the amount of time lost through bad weather is comparatively small in any business having appliances for use on dull days; the centres of our cities are, of course, exceptions, but the larger part of photographic work is not done in such localities.

We are also told that business comes in rushes, and at times it is necessary to work at a pressure, whilst at other times there is not enough to keep the staff fully employed; hence the assistant should give time when busy to compensate for time lost when slack. This, again, is a weak argument, for common sense tells us that an employer does not engage an assistant unless he has sufficient orders to keep him engaged at a profit. I take it, then, that any business employing assistants will not be troubled with the difficulty of finding them profitable occupation. A rush of business simply means that the firm is under-staffed, and the only remedy is to engage temporary assistance, since, as a rule, a workman cannot suddenly double, or even slightly increase, the amount of work he has been accustomed to produce.

There is another objection, that a photographic assistant cannot be tied to stated hours, nor throw down his tools on the stroke of the clock, leaving negatives and prints, &c., unfinished. This contains very little of practical moment, for any skilled worker can arrange what he has to do to correspond with the time at which his task is to end.

These and other difficulties are scarcely worth consideration, since the payment for overtime and the fixing of an hour rate would entirely remove them.

The first step towards such a reform is for assistants to recognise that the old relation of "give and take" is not what it was when the assistant had personal relations with his employer. The employer is rarely seen in modern workshops, the assistant dealing solely with a manager or clerk; this fact alone takes from the "give-and-take" notion all the meaning it at one time had, the outcome being that all considerations of equity are destroyed, because the manager or clerk, whilst exacting his employer's bond, cannot grant any privilege to the assistant. Under present conditions the contract is very unequal and unjust against the assistant, for, whilst it professes equity, it leaves the decision entirely in the hands of employers. The agreement runs that the *employees* shall leave when their work is done, the employer deciding when work is done and when not done, a position which results in some strange judgments.

To remove these abuses, the relation between employer and employed must be founded on a basis of strict equity. This at a stroke destroys all gratuities, *i.e.*, Christmas boxes, payment for holidays, time off, slack time, dull days, &c., on the part of employers; and from assistants unpaid overtime and other unpaid services, the assistant being paid only for the time he is actually at work.

To state the agreement more particularly, I propose, in short, a fifty-hour week at 9d. the hour, the hours to be from eight a.m. to six p.m. on five days of the week, with one hour for dinner, and from eight to one on a Saturday. The full week would thus mean 37s. 6d. in wages. All overtime, that is, all time beyond the hours specified, to be counted as overtime, and to be paid as time and a half, or 1s. 1½d. per hour, these hours and rate of pay to apply alike to operator, retoucher, printer, as the minimum for a competent hand. Payment being by the hour, an hour's notice to terminate the engagement on either side.

JOHN A. RANDALL.

### SENSITISING CARBON TISSUE.

ONE of the reasons why carbon printing is not so much practised as it ought to be lies in the fact that prints made upon home-sensitised tissue are always so much flatter and inferior to those made upon tissue bought ready-sensitised, and, as it is not always convenient to have to send to the makers for a fresh supply, many people leave the process severely alone, and use some other that gives them good results without any trouble. The true reason of this is that all the published formulae for sensitising carbon tissue give far too strong a solution of the bichromate of potash, *viz.*, three per cent. in summer, five per cent. in winter. These are both far too strong, and with any tissue will give flat results. The best strength for the purpose will be found to be one and a half per cent. in summer, two in winter.

There is, however, another factor in the process to be considered, *viz.*, the operation of drying the tissue. The slower it is dried, the flatter will be the prints, and *vice versa*; and, when once dried, it should be kept under pressure or in an air-tight box, as the action of air upon bichro-

mated gelatine (especially if moisture be present) is the same as that of light.

If attention be paid to above facts, good carbon prints can be obtained from any kind of negative, which is more than can be said of any other printing process. A very instructive lesson can be got out of the following experiment: Sensitise two pieces of tissue, one in one and a half per cent., the other in two per cent.; dry both as quickly as expedient. Take prints with both as soon as tissue is dry. Keep some for two, three, and four days, and compare the results. The first ones will be much too hard, the last ones will be either flat or getting that way.

W. T. WILKINSON.

### FABRICS FOR PHOTOGRAPHS.

MR. J. A. HARVEY has patented an improved fabric material, having a coating or surfacing of rubber on its back, and being on its face side sensitised with a photographic solution of the ferro-prussiate or other suitable kind or kinds.

The objects of the invention are:—

First.—To produce a photographic-print fabric possessing greater strength and durability than paper or other materials generally heretofore employed or in use.

Second.—A material that will not stretch or alter its proportions during the development process.

Third.—A material that will not partake of permanent fold or a tendency to roll up again when opened after having been kept rolled some time, and

Fourth.—A material that is unaffected, or does not become damaged by wet or moisture.

The portion of the figure referenced or indicated A is intended to represent the face or sensitised surface, usually more or less coloured,

the middle portion, indicated B, the face of the fabric material before being sensitised, and the portion indicated C is intended to represent the backing of rubber, the fabric material being removed to expose the same to view.

The backing of rubber is applied to the fabric, which must be of fine and uniform mesh or texture so as to not permeate the same fully or prevent the sensitising liquid or solution from being freely absorbed in the front surface. The fabric may be linen, cotton, silk, or very fine woollen or other material or textile. The backing must be pliable and waterproof and is preferably rubber, but a composition of non-drying oil, white lead, and other substances also fulfils this condition fairly well.

### LIQUID PRISMS IN CINEMATOGRAPHY.

THE use of liquid prisms in cinematographic projection has been patented by Messrs. Lumière. The following is an extract from the specification:—

The film, A, which carries the successive images, moves vertically from top to bottom, impelled by the roller, B, provided with points, which enter the regularly spaced perforations of the film. It is guided by known arrangements, and passes behind an opening, C, the height of which is equal to that of two consecutive images or pictures.

In front of this opening is arranged the object-glass, O, and, at the back, an ordinary lighting apparatus not shown in the drawing.

In front of the object-glass is arranged the prism, P, of variable angle, formed of two sheets of glass, A, A, with parallel faces, capable of oscillating separately on two horizontal axes, B, B. The sheets, A, are united at their edges by a rubber membrane, D, bellows wise, so as to constitute a liquid-tight box, at the same time leaving liberty of oscillation to the sheets. This box, filled with water, or other non-coloured liquid, the index of refraction of which is conveniently chosen, forms a prism, the faces of which can receive various inclinations, by means of levers, E, E, keyed on each of the oscillation axes, B.

The levers, *x*, are operated by a double cam, *n*, mounted on a horizontal shaft, *r*, receiving its movement from the drum, *b*, by means of helical gearing, *g* & *h*.

The cam, *n*, has the form of a drum, the two edges of which are symmetrically cut in helical form. The levers, *x*, bear on these edges by their interior face, the direction of which is parallel to the faces of the prism, and passes through the centre of oscillation, *b*. The levers are kept in contact with the cam by a spring, *k*.

The cam, *n*, makes one revolution during the passage of an image; its size and the speed of the helices are such that, in the middle of its

motion, the faces, *a*, *a*, of the prism are parallel (see fig. 3), and that at the extreme points of the motion (see figs. 2 and 4) they form in one direction or the other the maximum angle of deviation.

When the image, *i* (see fig. 2), occupies the upper part of the opening, *c* *d*, the angle of the prism, *p*, is greatest, and has its opening turned upwards. When the image has arrived at the centre of the opening (see fig. 3), the prism has its faces parallel, and the deviation is nil.

When at last the image has arrived at the lower part of the opening, the angle of the prism is greatest, and it has its opening turned downwards (see fig. 4).

It is therefore possible, by a convenient choice of the maximum angle of the prism, to cause to coincide on the screen the projections of the images in these extreme positions (see figs. 2 and 4, with its medium projection, fig. 3). In the intermediary positions the coincidence will necessarily take place, because by construction the linear motion of the image is proportionate to the angular tangent of the prism, and that the motion of the projection on the screen is proportionate to the angle of deviation of the rays. Now, these two angles, at least within the useful limits of size of the apparatus, obviously vary in the same proportion.

At the end of each turn the prism returns briskly from the position shown at fig. 4 to that shown at fig. 2, so that the new image, *i*<sup>1</sup> (fig. 4), may be projected in its turn.

The size of the extreme angles of the prism is fixed by construction according to the focal distance of the object-glass, but it may be made to vary within certain limits by lengthening or shortening the arms of the levers, *x*, so as to permit the regulation of the apparatus. This result is obtained by raising or lowering all the upper part of the apparatus comprising the opening, the object-glass, and prism, mounted for this purpose on a movable support, *m*. This regulation may take place during the working of the apparatus by observing the projections on the screen. The apparatus thus arranged can naturally serve for obtaining negatives of animated scenes.

The error committed in admitting that the deviation is proportionate to the angle of the prism is of less importance in proportion as the variations of this latter angle are smaller, hence a means of reducing this error by replacing the single prism by two or a larger number of similar prisms, the deviations of which unite together to obtain the total deviation.

The maximum angle of each of these prisms is thus diminished, as well as the error which results therefrom.

Each prism will in this case be actuated by a helicoidal cam, similar to the cam, *n*, but of a much smaller motion, which lessens the briskness of fall of the levers, *x*, at the end of each rotation.

## THE COLOUR OF BLINDS.

THE remarkable and widely varying properties of the elementary colours which compose white light suggest, says the *Lancet*, that the employment of screens as in the blinds placed over our windows should be founded on a scientific basis. Our knowledge of the properties of each individual section of the spectrum is not exact; but this much we do know, that the rays of least refrangibility, the red rays, are without direct chemical effects, they occur at the heat end of the spectrum. On the other hand, the rays of the highest refrangibility contain the violet rays, which chemically are exceedingly active. It is these rays which are concerned in photography, and, doubtless, also in the great processes of vegetable nutrition and growth. The object of blinds is, of course, twofold—to keep a room cool and to screen out some of the light, so as to avoid the bleaching of colouring materials of the carpets and furniture. At the same time sufficient light must be admitted, so that the occupant may see without difficulty. What, then, is the best colour for the purpose? Since light exerts the peculiar action due to the actinic rays, which materially and wholesomely affects the air of a dwelling-room, care should obviously be taken not to exclude all the rays that are so concerned. Thus ruby or orange-red material would be contra-indicated. Abundance of light is inimical to the life of micro-organisms, so that a material in some shape of a compromise should be selected. The best for this purpose is probably a delicately ochre-coloured fabric. This would screen part of the active light rays, and, if of a fair thickness, the greater part of the heat rays, while admitting sufficient active rays to allow of a wholesome effect upon the room and its surroundings. Venetian blinds do not allow of the graduation, which is desirable, of the tone of light that may be adjusted with cloth fabric. As is well known, exclusively red light has been used as a therapeutic agent, and apparently with encouraging results, in measles.

## AN IMITATION PLATINUM PROCESS.

Mrs. R. B. WEST, of Newhaven, Connecticut, has patented the following method of photographic printing:—

The paper employed may be of the usual character, and the sensitising compound consist of ammonium nitro-prusside, 25 parts; ammonio-citrate of iron, or, as it is sometimes called, a double citrate of iron and ammonia, 30 parts; and water, 100 parts. To this may be added small quantities of other citrates for the purpose of modifying the colour of the prints; for example, the citrate of magnesium to produce an engraving black, or the citrate of zinc for a brown. These, while not absolutely necessary for the success of the sensitising paper, are of use for producing certain tints. Other soluble nitro-prussides, such as sodium nitro-prusside or potassium nitro-prusside, can be substituted for the ammonium nitro-prusside, but they are not as sensitive to light as is the ammonium nitro-prusside, which is therefore to be preferred. Paper coated with this sensitising compound is sensitive to light, by exposure to which it becomes brown or black, so that, when exposed to light under a negative in the usual manner for printing photographs, a picture in light and shadow is produced on the paper. This print is then washed in water for two or three minutes to remove superfluous chemicals, and then subjected for five minutes to a bath containing a mordant like acetate of lead in a two per cent. aqueous solution, for the purpose of rendering the print permanent. For this bath any other well-known bath for fixing the print may be employed. No further manipulation is necessary except a slight washing of the print in water.

## STEREOSCOPY.

MR. L. PAXTON sends the following interesting letter to the *English Mechanic*:—

"The original stereoscope was invented by Professor Wheatstone about 1840. At that time photography was in its infancy, and the first stereos were such objects as cubes, cones, prisms, &c., drawn as they would be seen with either eye. The spectroscope was a reflecting one, consisting of two mirrors set about at right angles to each other, so that the images of the pictures placed at some distance on each side appeared to unite behind the mirrors. The angle at which the mirrors were placed could be adjusted for pictures of various sizes.

"About 1855 or 1856 I made some stereoscopic pictures of Indian

temples with an ordinary camera, taking pairs of pictures, shifting the camera about a foot between the pair. Some of the prints were sent to Negretti & Zambra to mount, and they requested me to do them a set, sending me a very perfect stereoscopic camera for the purpose. It had twin lenses like an ordinary binocular camera, the dark slides being square, so that two sets of pictures were made on one plate. The camera could also be set upright, fitting on to a system of parallel bars, an arrangement devised by Mr. Latimer Clark. The photographs were taken so that the right-hand picture was taken on the left-hand side of the plate, and so did not require to be shifted after printing; the camera, with slides, fitted into a box, on the top of which the shifting bars were fixed, the bottom of the box screwing on to the tripod stand. I have lately done some very satisfactory stereoscopies with a hand camera, making the exposures first from my right hip, and then from the left.

"I do not think that it is very generally known that stereoscopic pictures can, with a very little practice, be seen without a stereoscope. Perhaps the simplest plan of educating the eye is to place two coloured wafers on a sheet of white paper about two inches or rather less apart. On looking towards them the eyes will tend to converge and form one image. The distance between the wafers can be gradually increased till the eyes can unite them at two and a half to three inches apart.

"On first trying to unite stereoscopic slides, it is as well to select some with a marked feature, which facilitates the uniting the picture. After a short time, however, there is no difficulty, even if the slides are less marked. The magnifying power of the lenses of the stereoscope is a great advantage if the prints have much delicate detail."

## Our Editorial Table.

### A SPEED-TESTING FRAME.

Marion & Co., Soho-square, W.

MESSRS. MARION send us a neatly made speed-testing frame for use as a guide in the printing of quick and slow bromide papers, lantern slides, &c., the construction of which is made clear by the annexed illustration. It is also recommended for plates and papers. The frame has six sliding strips by which the sensitive surface may be uncovered and ex-

posed for the whole or part of the width of the frame. By using an artificial light and making a series of exposures at a stated distance in the following manner a good guide to the necessary exposure can be satisfactorily obtained. The instructions are as follows: Place a piece of paper or a plate in the printing frame, with its sensitive side towards the sliding strips, and facing the film side of a negative if one is to be used in the test. Now at, say, one foot from the light, withdraw the strips in consecutive order, leaving them withdrawn and timing the exposures respectively as follows:—

Nos.	1	2	3	4	5	6
Seconds	16	8	4	2	1	1

The total exposure given to each strip will be as follows:—

Nos.	1	2	3	4	5	6
Seconds	32	16	8	4	2	1

The sliding pieces may be withdrawn half way, and two exposures made on each, with exposures of such length and in such progression as the judgment of the user may dictate. A comparison of two plates or papers may be made so as to give a fair idea of their relative speeds. Assuming, for instance, that the plate or paper to be tested is supposed to be considerably more sensitive than the one tested in the foregoing example, make the exposures in exactly the same manner, but at two feet from the light. The exposures in this case will be equivalent to the following times:—

Nos.	1	2	3	4	5	6
Seconds	8	4	2	1	$\frac{1}{2}$	$\frac{1}{2}$

Supposing the density of strip No. 4 in test B is equal to that of No. 3 in test A, it will show that B is practically eight times as sensitive as A,

and under similar conditions will only require one-eighth the exposure. This speed-testing frame, it will be observed, is a simple piece of apparatus, based on plain and easily grasped principles, and its uses in arriving at correctness of exposure in several branches of photographic printing are so obvious that it should find a place in the equipment of every photographer.

### PHOTOGRAPHY ANNUAL FOR 1899.

Edited by R. CHILD BAYLEY, F.R.P.S. 314 pp. Price 2s. 6d.; cloth, 3s. 6d.

London: Iliffe, Sons, & Sturmer, 3, St. Bride-street.

THIS issue of *Photography Annual* is compressed into space which is considerably smaller than that of previous volumes, all matter of the nature of reprint from former *Annals* having been omitted; nevertheless, the characteristic features of the publication have been retained. Mr. C. H. Bothamley, as usual, summarises advances in photographic chemistry and processes during the past year, Mr. Chapman Jones deals similarly with photographic optics, and Mr. Bolas with photo-mechanical printing. Another familiar name is that of Mr. Albert Taylor, who writes of astronomical photography, while Mr. P. E. B. Jourdain is responsible for the sections on photo-micrography and radiography. There are a number of capital photo-mechanical illustrations, reviews of apparatus, a list of societies, a trade directory, and other information, thus making *Photography Annual* a very useful book of reference.

FROM Mr. Wilfred Emery, of 8, Dyne-road, Brondesbury, N.W., we have received a set of Convention photographs taken by means of the folding Ape—an excellent camera.

MR. EDMOND WALLIS, of Orpington, Kent, sends us a selection of photographs of backgrounds suitable for employment in taking pictures of little children. The designs are varied and fanciful, and for juvenile portraiture the backgrounds should be in considerable request.

## News and Notes.

PHOTOGRAPHIC CLUB.—September 13, at eight o'clock. Members' Open Night.

ACCIDENT TO A PHOTOGRAPHER.—A man named Elson formed one of a picnic party from the printing establishment of Messrs. F. R. Sparks & Sons, Leeds, to Boston Spa on Monday. The party ascended the hill known as Jackdaw Crag, and on the top Elson, whilst placing his camera, fell over the crag into the river, a distance of about 100 feet. He luckily fell into a deep pool and swam ashore. He was afterwards removed to the Leeds Infirmary, when he was found to be suffering from a fractured jaw and concussion of the brain. Elson is reported to be going on well.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—The annual Exhibition of this Society will be held at the Institute, 103, Borough-road, S.E., on Wednesday, Thursday, Friday, and Saturday, December 27, 28, 29, and 30. Entries close December 9. The open classes are: H, Prints previously medalled, 1 gold, 1 silver medal; I, Prints not previously medalled to December 9, 1899, 1 silver, 2 bronze medals; K, Lantern slides previously medalled, 1 gold medallion, 1 silver medal; L, Lantern slides not previously medalled to December 9, 1899, 1 silver, 1 bronze medal. Further information to be obtained of the Hon. Exhibition Secretary, Mr. E. J. Hoar, 59, Hillingdon-street, S.E.

AMERICAN GLASS.—A Transatlantic contemporary, remarking that the American glass industry is only forty years old, adds that some glass was manufactured in America prior to that, but most of it came from the old countries. It has only been within the last twenty years that the nation has really met her own demands, and it is but within the last five or six years that practically all foreign glass has been shut out. It is true that the old countries still excel in general lines of fine manufacture, but this is getting to be less and less the case every year. The great trouble of the American industry now is that it has gone to seed. Over-production marks every line, and it is an absolute necessity that manufacturers' combinations or trusts control the production to keep the markets from going to the dogs.

CHLORIDES IN SEA AIR.—M. Armand Gautier recently published in the *Bull. Soc. Chim.* some investigations which he carried on regarding the maximum quantities of chlorides contained in sea air. The experiments were made at the light-house of Rochecroix, in October 1898. The air was passed slowly by aspiration through a long tube containing glass wool previously washed and dried, so that any mass held in suspension was deposited; 341 litres of air, under a pressure of 760 to 767 millimetres, at a temperature of 16° C., were passed through this mass of glass wool, which was then taken to the laboratory and washed in a little warm water. The chlorides contained in the filter were estimated by a silver solution. A total quantity of 0.00462 gramme of chloride was found, corresponding to 0.0076 of salt, which, by calculation, corresponds to 0.022 gramme of sodium chloride per cubic metre of air. It is believed that this quantity, together with the traces of iodine which accompany it, give sea air the tonic quantities which characterise it.

**A PHOTOGRAPHER COMMITS SUICIDE.**—On Friday last the Coroner for West Kent investigated a case of drowning of a Manchester man named Alfred John Elliott, aged forty-seven, a photographer, of 85, Stamford-street, Old Trafford, Manchester. It appeared that deceased was formerly in an asylum. On the previous Monday he went to London by the Great Central Railway for the purpose of spending a few days with some of his friends. He arrived at his friends' in a very excited state without his luggage. From his conversation they discovered that he was suffering from the delusion that he was Sandow, the strong man, and it is supposed that this delusion cost him his life. He subsequently disappeared, and the next his relatives heard of him was that his dead body had been found in Crayford Creek. He is supposed to have walked all the way from North London to Crayford, and he was last seen swimming about the Creek half dressed. The widow of deceased stated that he had never shown any suicidal tendencies, and eventually the jury returned a verdict of "accidental death."

AMONGST the visitors to Christchurch recently was a gentleman whose name is of world-wide fame amongst photographers and others, Mr. Willis, the inventor and patentee of the platinotype process, who, in company with Mr. Humphrey (the manager of the Platinotype Company), was cruising round the south coast in his steam launch, the *Yuen-yuen*, of the Royal London Yacht Club. Mr. Willis and his companion, who appear to be friends of Mr. Mallett, were met in the harbour by him and piloted up to the Quay. We believe that this is the first time that a vessel of this kind and size has ever visited the Quay. The *Yuen-yuen* is sixty-five feet long, with a draught of four feet, and is beautifully fitted up with a forty-horse-power petroleum engine, which seems a marvel of mechanics, when it is considered that this amount of power is contained in a room about seven feet and five feet. There is very little vibration, smell of the oil, smoke, or steam to annoy the passengers, and, what is equally important, no fear of an explosion. The engine and boiler are unique of their kind, and are the invention of the engineer of the Platinotype Company.—*Christchurch Times*.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION AND CONVENTION SLIDES.**—During the past two months the meetings of the London and Provincial Photographic Association have been of an informal nature, but now a full programme has been issued for September, October, November, and December, which should prove of considerable interest to members. Commencing on September 7 with a demonstration of "Kachin;" other matters to be dealt with are: The Kromaz Colour Photography, the Tella Camera, Vicol, Wellington Film, and the Biokam. On September 14, the first Lantern Night, there is to be a display of Convention slides, and the Hon. Secretary, Mr. Walter D. Welford, will be greatly obliged if some of his Convention friends will assist him by sending him a few slides from negatives taken during the enjoyable week at Gloucester. He will take every care of them, and, if titles and producers' names are written on the slides, these details shall be given in full. Possibly some other London Society would like to devote an evening to them, and Mr. Welford will be pleased to give any assistance in this direction, and is willing to reciprocate by lending his own slides to any Convention for a similar purpose. His address is 19, Southampton-buildings, Chancery-lane, W.C.

THE Leeds Photographic Society have just issued the syllabus of meetings in session 1899-1900, which are to be held in the Philosophical Hall, Park-ro v, as far as practicable, on the second and fourth Tuesdays in each month, and the session gives promise of being in every respect an important one, and quite in keeping with previous programmes. A novel feature is the insertion of an extra leaf as follows: "Yorkshire Photographic Union.—Mr. —, being a member of the Leeds Photographic Society, is entitled to the privileges of an Associate of the above Union, and may attend any lecture given under the auspices of the Union, wherever it may be held.—J. Crossdale Comitas, Hon. Secretary." The session opens on September 26 next with "The Camera and the Wheel," by Mr. F. O. Byrnes (R. & J. Beck, Limited). On October 10 Mr. W. Thomas, F.R.P.S., will discourse on "Technical Control for Pictorial Purposes;" and on October 27 the President of the Batley Photographic Society (Mr. Percy Sheard) will treat of "Enlarged Negatives" (Yorkshire Photographic Union lecture). November 14, on "Lantern-slide Making" is the subject down for Mr. Godfrey Bingley (the President) (another Yorkshire Photographic Union lecture). Mr. J. W. Wade, of the Manchester Photographic Society, lectures on November 28 as follows: "In Search of the Picturesque." A tour in the English Lake district, Isle of Man, and North Wales, one other lecture, viz., on December 12, a demonstration by Mr. J. T. Sandell on "Theory, Practice, and Results with the Sandell Perfect Films and Plates (Multiple)," to be followed by the Annual Dinner, and on December 22 the Annual Meeting for the election of officers brings the first half of the session to a close with the end of the year. It is hardly necessary to say that the lectures are being looked forward to by the members with much interest.

**FORM AND HEIGHT OF CLOUDS.**—M. Antoniadi, F.R.A.S., and M. Mathieu, of the National Agronomical Institute, Paris, contribute to the September issue of *Knowledge* a profusely illustrated article on "Clouds." "The application of photography to the study of meteorological phenomena enables us to investigate with great advantage the form and height of the various clouds, the appearance of waterspouts, rainbows, halos, coronas, &c., as well as to record the fugitive sinuosities of the lightning flash. Nor does this mode of inquiry require any modification of the camera. A good large-angle object-glass, with an ordinary shutter, is all that is needed. For clouds, however, floating about the zenith, a movable-headed foot will be found of use. The simultaneous photography of the same cloud from two different stations will give its height above the earth's surface." A very instructive feature of the article consists in the reproduction and description of a photograph of a rainbow taken on June 2, 1898. "The photograph is interesting as showing the inner space of the bow to be much brighter than the outer, an appearance which is not always noticeable to the eye. This is due to the fact that, whereas no light is sent to the observer from the back of the drops situated outside the first and as far as the secondary bow, the drops inside the

primary do reflect light from their back, which, in spite of its enfeeblement through divergence, suffices to vaguely illumine the inner segment. This is the region of the 'supernumerary bows' unexplained by Descartes and Newton, but to which the illustrious Thomas Young, with the intuition of genius, applied his discovery of the law of interference of light. The condition necessary for the appearance of the supernumeraries is that the drops shall all be of nearly equal sizes. Otherwise, as in the case of the photograph, we have a confused superposition of the various colours, which are thus blended into white light."

## Patent News.

THE following applications for Patents were made between August 21 and August 26, 1899:—

FILM-HOLDER.—No. 17,028. "Improved Frame for Holding Photographic Films." C. BOUSSEAU.

FILMS.—No. 17,098. "A New or Improved Process of Producing Photographic Films." Complete specification. J. MEYER.

FILMS.—17,164. "Improvements in Photographic Films and in the Manufacture thereof." J. E. THORNTON and C. F. S. ROTHWELL.

FILMS.—No. 17,165. "Improvements in Transparent Photographic Films and in the Manufacture thereof." J. E. THORNTON and C. F. S. ROTHWELL.

FILM-COATING MACHINERY.—No. 17,215. "Improvements in the Method, Means, and Apparatus for Coating Photographic Paper Films and the like, and in the Manufacture of Photographic Materials." J. E. THORNTON and C. F. S. ROTHWELL.

EMBOSSING PHOTOGRAPHS.—No. 17,280. "An Improved Method of Preparing Embossed Photographs, Artists' Post Cards, and the like." Communicated by F. von Manger. E. EDWARDS.

DEVELOPING AND FIXING.—No. 17,292. "Improvements in Photography and connected with the operations of Developing and Fixing." J. E. THORNTON and C. F. S. ROTHWELL.

STEREOSCOPIC PHOTOGRAPHY.—No. 17,223. "Improvements in relation to Stereoscopic Photography." J. E. THORNTON.

ROLLING PRESS.—No. 17,307. "Cylinder or Roll-press for the simultaneous Staining and Mating, without heat, of Photos and similar articles of Graphic Art." A. H. ANDERS.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sep-ember.	Name of Society.	Subject.
12.....	Hackney.....	Platinotype Demonstration. Platinotype Company.
13.....	Photographic Club.....	Members' Open Night.
13.....	West Surrey.....	Affiliation Lecture: Bromide Enlarging. J. H. Gear, F.R.P.S.
14.....	London and Provincial.....	Lantern Night: Gloucester Convention Slides.
16.....	Borough Polytechnic.....	Excursion: Orshott and Esher. Leader E. J. Hoar.
16.....	Hackney.....	Excursion: Ponders End. Leader, S. Stean.
16.....	West London.....	Excursion: Westminster to Chelsea.
17.....	South London.....	Sunday Excursion.

### PHOTOGRAPHIC CLUB.

AUGUST 30.—Mr. Charles Wallis in the chair.

MR. W. D. WELFORD showed some film negatives of Egyptian scenes taken with the Tella hand camera, jocularly asking for an explanation of certain marks thereon, to disguise the real fact that the negatives were taken at a panorama in Belgium, representing Cairo, which, however, was not suggested by the negatives themselves, except on very close inspection. He spoke appreciatively of the Tella camera. He also showed a number of films which he had taken in Belgium with the biokam, a small cinematograph apparatus. Some time ago he had shown this apparatus in action. The film was twenty-five feet long, but the pictures were only half the linear dimensions of the ordinary or standard film; thus the user was able to get an effect equal to that given by the larger apparatus. Each film bore about 700 separate exposures. To develop these films, of course, a large quantity of solution was required, and, for reasons dictated by a desire to economise, he used the accumulated used solutions of ortol, which he required for ordinary work, and added water up to forty ounces. It was slower than when normally compounded, but served the purpose admirably. Mr. Welford likewise passed round a collection of photographs of the Van Dyck procession at Antwerp this autumn, and a group of those taking part in the late excursion of the South London Society to Belgium, with the five Belgian gentlemen who acted as guides at the Botanical Gardens in Brussels.

MR. WELFORD, in the course of some remarks about the ortol developer, said that it exercised a very strong continuing action, one that he had utilised in several ways. It was very difficult to arrest the action of this developer in the

film, and, if one wished to stop density instantly, the plate had to be plunged into the fixing bath. It was a very simple matter to get extra density by holding the plate under the water tap for a while. As soon as the image showed in a plate he had also finished development by transferring the plate to a dish of plain water or holding under the tap. Other developers he knew had a continuing action, but to nothing like the extent of *ortol*.

**Cripplegate Photographic Society.**—September 4.—Mr. Donald A. Nightingale, representing Messrs. John J. Griffin & Sons, Limited, gave a demonstration of

#### KACHIN AS A DEVELOPER.

The lecturer described Kachin as a benzine derivative, bearing in its action on a photographic plate a close resemblance to pyrogallol, but differing markedly in its stability towards light, its resourceful powers as a developing agent, and good keeping qualities. Plates were developed, having been exposed four times the correct time, which, by the addition of bromide, appeared with clear shadows and full density. The combined kachin-hypo development was then demonstrated with great success, this method producing the over-exposed negative with even greater clearness and vigour than the correctly exposed plate possessed. This effect was considered to be due to physical development, which continued after the plate had become apparently fixed. In reply to a question it was stated that with kachin the image appeared rapidly, bringing out nearly all detail at once, and then gathered density more leisurely. This enabled the worker to remove the plate at any time, and so obtain the precise density he required at will.

#### FORTHCOMING EXHIBITIONS.

1899.

- Sept. 22–Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- „ 25–Nov. 11..... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.
- October 18–24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.
- „ 22–Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- Nov. 27–Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7–9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.
- „ 27–30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

#### MARKINGS IN NEGATIVES.

To the Editors.

GENTLEMEN,—I wish to draw the attention of photographers to an unsuspected cause of finger markings on negatives. These marks caused me a good deal of annoyance in the recent hot weather, so much so that I complained to the plate-makers (one of our leading firms). They disclaimed responsibility for the markings and suggested that some method of working on my part was the cause.

I pointed out to them that we never in our practice touched the surface of the film with our fingers, and yet the strange marks appeared. I opened box after box of plates, took out one from each box, and exposed,

and no sign of marks; yet, immediately we had a large batch to develop, up they came smiling. I resolved to send back the remainder of the batch of plates, and the plate-makers kindly agreed to send me others for them. They appeared in force in the new batch, and I was forced to believe that, somehow or other, the fault was on our side. As they appeared at intervals only, I watched carefully under what conditions, and I found that it was only in hot weather, and only when we had been very busy and had a lot of sitters, also that if development was postponed till the evening or the morning of next day. Suddenly I bethought me of our method of packing the plates, and herein found a complete solution of the mystery. Our practice was to fill the slide, expose, change, putting the plate film down on the glass side of the plate below until the box was full. In hot weather, on a busy day, this was done so rapidly that the perspiration on the back of the plate from the fingers in adjusting the plate into the slide had not time to dry off before another plate was placed on the top of it, thus sealing the wet perspiration between the plate and film; this, with the pressure of the plates on each other, caused the drops of moisture to be squeezed out a little, producing the peculiar want of sharpness in the finger marks, and, as it were, pressing them into the film. Then, again, the action of the moisture only appeared to be detrimental if it got any length of time to act, hence their appearance when the plates lay all day before being developed. By packing the plates film to film all signs of the marks disappeared. The plates were all alike perfectly clean. As I know several photographers who have been troubled with these marks, I thought it right to enter at length into the matter, through your courtesy.

I should also like to hear if any others have been troubled the same way. The plate-makers seem to consider the matter of some importance, as it, no doubt, in some cases has caused them to be blamed innocently. I send you a negative showing the marks. Perhaps you have seen some like them.

Thanking you in anticipation,—I am, yours, &c.,

JAMES NORVAL.

123, New-row, Dunfermline, August 31, 1899.

#### THE CAMERA CLUB JOURNAL AND THE PHOTO-MINIATURE.

To the Editors.

GENTLEMEN,—Re closing sentence of last *Ex Cathedra*, THE BRITISH JOURNAL OF PHOTOGRAPHY, August 11: "The editor of the Camera Club Journal sharply criticises an American publication for treating somewhat perfunctorily of hand-camera work." Ward and I are putting considerable hard work into the *Photo-Miniature*, and hence "felt" the hasty critique in Camera Club Journal of which you speak. Kindly glance over enclosed copy of letter sent to editor of Camera Club Journal, and judge of the reasonableness of his critique.—I am, yours, &c.,

JOHN A. TENNANT.

Tennant & Ward, Publishers.

289, Fourth-avenue, New York, August 19, 1899.

"August 15, 1899.

"To the Editor of the Journal of the Camera Club, London, England.

"DEAR SIR,—Permit a few words of explanation ament your criticism of 'Hand-camera Work' (No. 3, the *Photo-Miniature*) on pp. 119 and 120 of your August issue. You say therein: 'It is good as far as it goes, but it does not go far enough. It treats almost exclusively of the film hand cameras that one identifies with America. It describes the working and construction of these instruments with considerable detail, but says little or nothing of the plate hand cameras of European make, with which really good work can be done.'

"The facts are as follows: In the monograph of forty-one pages less than three and a half pages are devoted to film cameras and the manipulation of films. This proportion cannot be said to be excessive when the popularity and undoubted convenience of film photography are considered. It should also be remembered that hand cameras using roller or cut films are quite as generally employed in England as in America. In fact, the little book was written for the plate hand-camera worker, and film photography was given as small a portion of the space as was consistent with its present and probable future popularity.

"Further, in describing the various sorts of hand cameras, the information given was written to be equally applicable to European and American instruments. With one exception (a plate camera), all the instruments mentioned in the work are obtainable in the English market. The fact that England hand cameras of special manufacture were not specially mentioned arose from the complete failure of English manufacturers to respond to our request for information concerning their manufacture.

"A glance over the few pages of the book will show that its contents concern the plate hand camera fully as much or more than the film instrument. Thus pages 1 and 2 are given up to a general introduction to the subject, pages 3 and 4 to the Choice of a Camera and Essential Features. In these the film camera is not mentioned, except as follows: 'Others, taking up photography in a more serious way, or perhaps, with some little knowledge of its methods, seek a camera in the use of which they may combine pleasure and usefulness for a definite purpose. In such cases expense should be subordinated to the fitness of the instrument for the purpose in mind, and a "folding" or "film" camera, with suitable movements or "attachments" is indicated.' Surely

this mention of the film instrument was reasonable and just. Pages 5, 6, 7, and 8 are devoted to Fixed-focus Cameras, The Meaning of Fixed Focus, and Varieties of Fixed-focus Cameras. No mention of films is here made, except the assertion that many cameras of this type may now be had in which roller or cut films may be used as well as plates. This assertion is amply supported by facts. Pages 9 and 10 are given up to film photography almost entirely, under the captions Cartridge Films, Cut Films, and the Keeping Quality of Films. Of the reasonableness of this I have already spoken. The pages following this treat of the subjoined divisions: Adjustable Focus and Folding Cameras, Portability, Focussing Screen and Swing Back, Folding Front and Focussing Scale, Estimating Distances, View-finders, Reflecting and Twin-lens Cameras, Testing the Finder, Angle of View, Rising and Falling Front, Lenses, Anastigmats, Experiments, Exposure Shutters, Tripods. Knowing your Camera, Blue Spectacles, How to Hold the Camera, Exposure, A Common Fault, Exposure Factors, Plates, Comparative Light Values, Exposure Guides, Eder's Exposure Table, Stops and Exposure, Development, In the Dark Room, Over and Under-exposure, Formulae, Tank Development. In all these twenty-six pages there is no mention of films. The thirty-seventh page is wholly devoted to the development of roller films—a difficult matter, well worthy of the space given up to it, as all users of film cameras will agree.

"The thirty-eighth, thirty-ninth, fortieth, and forty-first pages (and) are occupied with When to Stop Developing, Cooling the Developer, Fixing, Intensification and Reduction of Negatives, and a list of books useful to the hand camerist.

"The essential preliminaries of hand-camera work being thus fairly and fully explained, the writer of the monograph informed his readers that the choice and treatment of various subjects would be dealt with in a future number (No. IV.: 'Photography Outdoors') of the *Photo-Miniature*.

"Again you say: 'The pamphlet reads more like an advertisement for a particular make of camera than a guide to hand-camera work generally.'

"I am peculiarly sensitive to this critique, which I consider manifestly unfair, and damaging (even in its untruth) to the *Photo-Miniature*. Perhaps it is difficult to avoid such a criticism in publishing a work wherein commercial articles in common use are described by name. Nevertheless, this description was deliberate, and honestly presented for the information of the reader, prefaced by the following explanation on the second page of the monograph.

"And, since hand-camera work to-day is inseparably connected with apparatus and conveniences which are articles of commerce, I will freely mention such instruments and helps as are pertinent to the matter in hand, without fear of being accused of indulging in advertisement, which, as a matter of course, I desire to avoid in these pages.

"Surely this explanation, and the reasonableness of its argument, should be sufficient to prevent such an unjust criticism as the one quoted—whether from a reader of the work or a reviewer.

"Finally, you say: 'We notice one serious mistake among the essential parts to a hand camera, which should be insisted upon, is mentioned a swing back. Every experienced worker knows that a swing back is not only unnecessary, but it is an absolute drawback in hand-camera work.'

"Against this I quote from the work itself: 'Among other essentials I may mention . . . double swing back for all cameras for plates larger than 4x5 inches' (page 4).

"And again, in the paragraph devoted to 'Focussing Screen and Swing Back,' the writer says:—

"A 'swing' is rarely needed in cameras for plates less than 5x7 inches. The swing movement is not by any means an essential feature for strictly hand-camera work, and, personally, I have found it more bother than it is worth, save in exceptional cases, and then it is very useful—as in architectural work.

"This, I believe, fully acquits the writer of 'Hand-camera Work' of the 'serious mistake' imputed to him by your reviewer. As every 'experienced worker' knows, the man who finds himself obliged to photograph a building in a narrow street, and cannot get further back than the entrance-step to the house across the way, will need a swing back, even on a 4x5 hand camera, to get the lines of his building true in the photograph. The occasional usefulness of the swing back in instruments for plates 5x7 inches or larger is a plain fact which no 'experienced worker' would care to deny, if he valued his reputation. Of the disadvantages of the swing back in strictly hand-camera work, the *Photo-Miniature* is explicit.

"Trusting that you will, as a matter of justice, find space wherein to put this explanation before the readers of your valued *Journal*,—I am, yours, &c.,

JOHN A. TENNANT.

## THE VALUE OF LENSES.

To the Editors.

GENTLEMEN,—Ament the remarks of "Free Lance" on the "small margin of loss" re lenses with an unknown name v. Ross or Dallmeyer, and selling the same second hand, let me tell him, I have had a little experience in these matters, and can assure him he is "out of it entirely." The "margin of loss" is, as a rule, considerably more than the first cost of the "unknown." Take, for instance, a best quality French make half-plate R.R. lens, and pit it against an English ditto. I have tried both, and found very little difference in the quality of the negative. Now, let "Free Lance" sell the two second hand, both in similar condition, he will soon find where the small (?) margin of loss is. The loss on the former at the outside would not be more than 17s. 6d., whereas he would do exceedingly well if he lost no less than 2l. on the latter.—I am, yours, &c.,

LENS.

## HOT-WEATHER PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—In your number of July 28 I see that "Cosmos" apparently approves the giving up of practical photography in England when the temperature rises to 80° or 90° in the dark room, and it makes me wonder what he would say to "practical photography" in India (southern) where one's dark room practically never gets down to the above temperature!

Just to encourage the dilettante amateur, who feels it "too hot even to talk" at 80°, I should like to give a *résumé* of an Indian amateur's work during the month of June last: Firstly, he travelled 2000 and odd miles by rail with the thermometer in the carriage showing daily temperatures up to 108.5 for many hours in the day, cooling down to 99° by ten p.m., when it was time to turn in for the night. The journey took five days, and, on arriving at his destination (where he stayed three weeks), he found that the first ten days presented nothing but dust, heat, and haze, while the remainder, for a variety, exhibited nothing but mist and rain.

During the three weeks he went out some ten times with his camera, and on three occasions his attempts were carried on under an umbrella with a maoinioah over himself and camera, while the rain simply came down in sheets, at about the rate of five inches an hour.

He exposed altogether four dozen plates and then packed up, returned the 2000 miles, and within three days had developed the lot; the ordinary shade temperature was a good bit over 100° every day during development, but what it was in the dark room could only be guessed by the state of moisture (inside and out) in which this amateur passed the hours of toil.

Within ten days he had printed some twelve dozen silver prints from these negatives, and, in addition, a complete set in platinum for himself—the others were to give away.

Out of four dozen exposures forty-four negatives are good enough to print from, and I send you a few of the good and indifferent to look at.

To finish my tale, this unfortunate (so "Cosmos" would apparently call him) amateur didn't think he had done anything out of the way.—I am, yours, &c.,

August 16, 1899.

PHOTOGRAPHY OVER 100°.

## PHOTOGRAPHY IN THE BRITISH MUSEUM.

To the Editors.

GENTLEMEN,—For some time past you have been agitating for increased facilities for photographing at the British Museum, and during the past week or so I notice the *Times* has also taken the matter up, and considerable discussion has been going on in their correspondence columns. One of the letters is contributed by Mr. Horace Hart, of the Oxford University Printing Press, who claims that the University authorities have solved the difficulty at the Bodleian Library here. Now, I don't suppose for a minute that the writer wishes to mislead any portion of the public in this matter, and yet his letter is decidedly misleading, for, instead of providing "increased facilities" for photographing in the Bodleian Library, the Curators have practically given a trade monopoly to the photographic department of the O. U. Clarendon Press, and closed its doors to local professionals. I sincerely hope that this lead will not be followed by the British Museum authorities, and trust that the Royal Photographic Society will give the matter their close attention, and see that photographers, both amateur and professional, will not be deprived of the advantage of being able to take their own negatives when they choose to do so.—I am, yours, &c.,

HENRY T. LEACH.

8, Turl-street, Oxford, September 1, 1899.

## THE HUDDERSFIELD EXHIBITION.

To the Editors.

GENTLEMEN,—The Committee of the Huddersfield Municipal Art Gallery have approached our Society with a view of holding an Exhibition of pictorial photographs to consist of a loan collection and an open class (no awards will be given) on similar lines to those adopted at Bradford last year.

Our Society has decided to accept their invitation, and, with a view to assisting them, has appointed a committee to work in conjunction with that of the Art Gallery.

It is proposed to open the Exhibition on December 11, for a period of six or eight weeks.

We are about to communicate with all the best-known workers, and shall be glad to be favoured with your assistance both personally and through the columns of your paper. All communications may be addressed to

W. A. BEVERES (President).

Cloth Hall-street, Huddersfield, September 4, 1899.

## Answers to Correspondents.

\* \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.*

\* \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* \* *Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

### PHOTOGRAPH REGISTERED:—

W. J. Gray, 171, Cromwell-road, Peterborough.—*Photograph of threshing operations.*

VIEWED; D. E., and others.—In our next.

BAZAAR.—The only thing we can suggest is a summons for illegal detention of the photographs. Matters such as this are best dealt with through a solicitor.

ADDRESS WANTED.—STEREO asks, "Will you please let me know the address of Underwood & Underwood, stereoscopic-view publishers (the London address)?"—In reply: 26, Red Lion-square, W.C.

R. M.—1. You are not liable in the circumstances, but you run some risk, as the photograph may be registered at any time and then an action might lie. 2. Yes; but at some risk, as above indicated.

D. G.—In a case such as that described legal action is the only thing we can suggest. Write the man with a threat to sue him for the detention of the negative, and we have no doubt it will be forthcoming.

DISPUTED AGREEMENT.—AZO. Better consult a solicitor. From what we can gather from your letter, the law is in favour of the operator, and against you, and we may say, if we can say it without giving offence, we hope it is.

COPYRIGHT.—DOUBTFUL. Under the circumstances it would not be the slightest use to register the copyright with the view to legal proceedings. As the author of the work (your father) has been dead over seven years, the copyright has expired.

D.—1. You would find the adaptation of incandescent gaslight for portraiture both safe and easy. 2. Messrs. Thorn & Huddle, of Tothill-street, Westminster, make a speciality of the acetylene light for photographic purposes. Better write them for particulars.

BOOKS WANTED.—PRO says: "Would you be so kind as to inform me of (1) a good book on posing and lighting in studio, and also (2) a book on retouching?"—In reply: 1. Messrs. Dawbarn & Ward publish such a book by Inglia. 2. To be obtained of Messrs. Marion & Co., Soho-square, W.

DISCOLOURED PLATINOTYPE.—S. R. J. sends us a vignettéd platinotype print in which the lights have become discoloured, and asks the reason, or whether it is not a "bromide." The print is a platinotype, and the cause of the discolouration is that it was imperfectly fixed—i.e., the iron salts not thoroughly removed by the acid baths.

RED TONES ON BROMIDE PRINTS.—DOWNTONIAN writes: "I wish to produce some bromide prints in Bortolozzi tint (red). Will you give me a hint how to do this?"—In our issue for March 24 is an article by Mr. E. W. Foxlee on the production of colours on Velox. Probably the formulae there given will answer with the paper you are using.

STEREOSCOPIC PHOTOGRAPHY.—W. BRAL asks: "If I copy a half-plate landscape or portrait with a binocular camera, ought I not to get a picture that would show the usual stereoscopic relief when viewed in the stereoscope? I have tried it, but find such is not the case."—That is only what was to be expected. Two dissimilar pictures from a flat surface cannot be expected to show stereoscopic relief.

CRAZY COLLODION.—G. BOOKER sends us a glass plate, coated with enamel collodion, which he made himself, and asks the cause of the crazy-like surface. The cause is that the collodion was made with solvents that were not strong enough, i.e., contained too much water. If ether, with a specific gravity of .730, and spirit of .829 be used, there will be no crappiness in the film, supposing, of course, that a good sample of pyroxyline is used.

ENAMELLING.—G. FULLER says: "Would you kindly inform me the proper proportion of ether, collodion, and alcohol for making the mixture used in the enamelling process?"—Equal parts of ether and alcohol. The specific gravity of the former should not be more than about .730, and the latter .820. By collodion we presume pyroxyline is meant. The proportion of that depends upon its character, but about six grains to the ounce of solvent will be about right.

COMMENCING BUSINESS.—E. HOLBECK writes: "Will you kindly tell me whether you would advise me to begin a photographic business in October with the dull winter in prospect, or would it be better to wait until the spring, when brighter days might bring more sitters?"—Something must depend upon the neighbourhood. If you commence now, you will have the opportunity of making the quality of your work known before the bright weather sets in and more sitters are to be had. You will then have saved time in establishing yourself before the busy season commences.

STUDIO BUILDING.—W. H. R. says, "I am going to put a glass roof into a top room, there is already a good side light, so the walls would be left undisturbed. Should I have to give any notice to the town surveyor, as if not it would save the fee?"—We should think not under the circumstances, as there would be no structural alterations. Something may, however, depend upon the by-laws of the town council, and whether the alterations can be seen from the street.

REMOVING VARNISH FROM NEGATIVE.—T. COPPING. Yes, the varnish can be removed. Supposing it be the ordinary negative varnish, the solvent of which is alcohol, proceed as follows: Place the negative in a dish of methylated spirit, and let it soak for an hour or so, then rub the surface with a tuft of cotton-wool. If this does not get the varnish off, repeat the soaking in fresh spirit, and, if it is still refractory, add a small quantity of caustic potash to the spirit and repeat the treatment.

ARTIFICIAL LIGHT FOR STUDIO.—S. J. says: "I want to take portraits at night in my studio, but I want a cheap, yet good, light for the purpose and free from danger. The electric light is, no doubt, the best; but that is quite out of the question with me, on account of the cost."—In reply: We should, in this case, recommend the flashlight—magnesium powder, used in one or other of the lamps advertised for the purpose. That is free from danger and yields a good light.

IMPERFECT FIXATION.—R. & G. say: "Herewith we send you a couple of views that have been in our show-case all the summer. You will see that the skies have turned to a faint purple brown. The prints were made on —'s P.O.P. Is it usual for this paper to go in that way when exposed for a few months to a strong light?"—No, unless, as in this case, the prints are not properly fixed. With any paper, if the prints are not properly fixed, they will discolour with a prolonged exposure to light.

REMOVING LEAVES FROM A TREE.—SHADOW says: "Can you tell me of a chemical that would, when dissolved in water and squirted over the leaves of a tree from a syringe, kill those leaves? If this is not a photographic question, it is a photographer's question, and is mixed up very much with the result of his work. I shall therefore feel obliged if you can help me."—We have had little experience in this direction, but we imagine that diluted sulphuric or hydrochloric acid would kill the leaves; so, we expect, would a solution of a caustic alkali, such as caustic soda or caustic potash.

DISCOLOURED METOL.—S. A. says: "I have been recently making up formulae for bromide work, but, on dissolving the metol, the solution turned brown, attaining in a few hours the colour of port wine; I have tried twice, but with same results, and even some developer the local chemist made for me went the same. I have thoroughly washed the bottles and measures, and cannot account for it. Can you suggest the cause?"—If the solution was made according to the recognised formulae, we cannot account for the trouble, unless the solution was made in dirty vessels or the sulphite of soda was at fault.

WARPED DARK SLIDE.—C. C. C. writes: "The other day one of my dark slides accidentally fell into the washing tank and was not discovered till some hours afterwards. It was then wiped and stood open in the sun to dry. Now, one of the shutters is so warped that it will not close with any amount of persuasion. Can you tell me what to do with it?"—The simplest thing will be to send the slide to the maker to have a new shutter. You might, however, try this: remove the shutter from the slide and soak it in water for an hour or so, wipe it, and then let it dry slowly under pressure, so as to keep it flat the while.

COUNTY COURT PROCEDURE.—E. L. says: "I have several customers in many parts of the country who are in my debt for large and small accounts, and should be obliged if, through your Correspondence columns, you would inform me whether I can send summons through the post, or whether it is imperative that I should take summons out in debtor's district, say Leicester."—In reply: We have not much experience of county-court business, but we believe you take out the summonses in your own district and have them locally served on the debtor, wherever he may reside. However, ask the registrar or some other official of the county court nearest to you, and he will put you in the way of the correct procedure.

CHLORIDE OF GOLD.—STEVEN says: "1. I have been making gold chloride with powdered gold—hydrochloric, 4; nitric, 1. How many grains of this gold should I use to be equivalent to the commercial chloride of Johnson's? Also best way to neutralise the solution? 2. Some years ago I made the neutral oxalate of potassium by mixing two chemicals. Can you give me formula? 3. I have a solution of metallic gold they contain. Presuming the gold you use is pure, the calculation is easy for the quantity you dissolve at a time. Neutralise with a little pure carbonate of lime. 2. Mix together a solution of oxalic acid and one of carbonate of potash, until the solution is neutral, then crystallise."

VARIOUS QUERIES.—CONDENSER says: "1. Will plain zinc dishes stain bromide enlargements (I mean for developing, fixing, and washing)? 2. Would you kindly give me a pyro-soda formula for stand development of instantaneous exposures? 3. I have an enlarging lantern, in which I burn acetylene gas. The condenser is only a four-and-a-half inch. Could I enlarge without a condenser by diffusing the light with ground glass or other means, as this condenser is not, of course, large enough for a 5 x 4 or half-plate?"—1. Zinc dishes are not suitable for hypo solutions, as the metal decomposes the hypo. Neither are they for photographic purposes generally, unless the metal is protected with an inert varnish. 2. See pages 284, 285 of the ALMANAC. 3. Yes, but the exposure will be very prolonged, as several thicknesses of the ground glass would be necessary to equally diffuse the small strong light of the acetylene. We should advise you to get a larger condenser.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The formulæ will be revised where necessary, and the latest de-

partures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

THE private view of the Royal Photographic Society's Exhibition takes place on Saturday September 23. The usual *Conversazione* will be held on the evening of the same day, and the Exhibition opens to the public on Monday week, September 25.

\* \* \*

WE understand that over eleven hundred photographs, &c., were last week sent in for the Exhibition. Upon being passed before the Selecting Committee we are informed that about two-thirds of the number were rejected. The fact that such a large collection of work was submitted for exhibition—and we are under the impression that it is the largest offered to the Society for several years past—clearly shows that there is no diminution of the general desire on the part of photographers to have their work hung at the most important and representative Exhibition of the year.

COLOUR PHOTOGRAPHY will probably figure rather more prominently than usual at the Exhibition, Messrs. Sanger Shepherd and E. Senior having sent in examples by the superposed film and Lippmann processes respectively. The Apparatus Section is likely to be larger than hitherto. With regard to the pictorial exhibits, if we may come to a general conclusion as a result of an inspection of a considerable number of photographs submitted to the Selecting Committee, we should say that the Exhibition will be good and level in quality, and free from the sombre eccentricities and monstrosities of portraiture which disfigured last year's display. The time has gone by when we looked for something startling or sensational at Pall Mall, and we can scarcely anticipate anything of the sort this year. Nevertheless, we have no doubt that the Exhibition will not fail to keep up its reputation for giving photographers material for much discussion and disagreement during the coming months.

AND, indeed, quite a promising start has been made in the printed war of words which annually acts as a kind of accompaniment to the progress of the Exhibition. We believe that our own contributions to these discussions never lack candour and frankness. The plainness and impartiality of criticism with which we are enabled to invest our references to the Exhibition and its system of management could only proceed from that complete disinterestedness of position which we alone of the weekly photographic press consistently occupy towards the Exhibition. In this matter we have always sought to keep a free hand. We have year after year refused nomination for the office of Judge, and we have declined to co-operate in the hanging or selection of the pictures. We have been guided in this policy by a desire to be absolutely unfettered in our critical treatment of the photographs hung on the walls; and, moreover, while we have prized the opportunity of taking this unbiassed and independent view of matters, we have also been animated by a keen anxiety not to place before the readers of this JOURNAL any criticism or opinion which was not the deliverance of an impartial mind, entirely uninfluenced by views formed in the exercise of the office of judge, selector, or hanger. In fine, we regard the annual Exhibition of the Royal Photographic Society as of such prime importance to the photographic world that we consider participation in its management as incompatible with that perfect freedom of critical comment which the readers of a photographic journal naturally look for.

THIS attitude of absolute independence towards the Exhibition is, we believe, greatly appreciated by our readers, who annually make us the recipients of many kindly recognitions of our outspokenness. It was from this point of view that a fortnight ago we considered it our duty to commend the action of the Society in denying to the Judges of its Exhibition the right, hitherto perfunctorily exercised, of revising the work of the Selecting Committee and going over those photographs which the latter body had considered ineligible for exhibition. In recent years it has been hard to discover what benefit accrued to the Exhibition by the inclusion of the Judges among the Selecting Committee, unless it be that it gave opportunity to one, or at most two, of those gentlemen to place among the exhibits a few of the hundreds of rejected photographs which accorded with their own personal predilections as to what

constituted presentable work in pictorial photography, and of rejecting those which did not—not an unmixed benefit. In this respect, if we are credibly informed, the Judges were of little or no practical assistance in the real work of selection beyond the extent indicated.

BUT, on the other hand, the Society's Exhibition suffered positive harm and indignity by conceding to some of the Judges this privilege of selection. Two or three gentlemen elected to serve on the Royal Photographic Society's Jury have also officiated as members of the Selecting Committee of another and contemporaneous Exhibition, and it is an open secret that the knowledge of what was sent into Pall Mall was utilised in a variety of ways scarcely to the advantage of the older Exhibition. In other words, there was the humiliating spectacle of the organizers of a rival and unfriendly Exhibition, conducted on entirely irresponsible lines, having a "finger in the pie" of the one great representative photographic Exhibition of the year held under the auspices of the principal photographic society of the world. We have a mass of evidence to prove the great dissatisfaction which existed amongst contributors to the Royal Photographic Society's Exhibition—and especially amongst members of the Society—at the co-operation of those self-constituted leaders of "pictorial" photography, whom the complaisance of a trustful electorate has permitted to have a hand in the affairs of a Society with which they are entirely out of sympathy. It is no secret that last year at least two of the awards gave the very greatest dissatisfaction indeed, and a repetition of a similar course of action this year will surely provoke a protest.

THIS year it was decided that the Selecting Committee should do the entire work of selection. As we have hinted, there were good grounds for this decision. It appears to be overlooked by some persons that the Royal Photographic Society is entitled to manage its Exhibition in the way it thinks best calculated to promote the objects of the Society and the interests of its exhibitors. The idea that it is likely to amend its regulations at the hysterical admonition of total outsiders, chagrined to find that they are not to be permitted to do as they like with the work of photographers not oversollicitous for their intervention, is too absurd for a moment's consideration. If any of the Judges were (or are) dissatisfied with the conditions under which they are asked to judge the Exhibition, there is no law which compels them to officiate. They can decline to act. So far as we know, they are not bound to serve against their will. The prospectus has been before them for some months. It clearly and concisely indicates their functions in the first line of the fourth paragraph, "Medals will be placed at the disposal of the Judges." The duty of these gentlemen is obviously to award or withhold those medals at their discretion. We take it that, if any one of them, even at the eleventh hour, should find himself unable to perform that duty, his colleagues will cheerfully release him from his obligation.

OUR readers may take it from us that a recent scream that the contributors to the R.P.S. Exhibition have been "hood-winked," because some of the Judges have been rigidly confined to the duties they were chosen to perform and not allowed

to participate in the selection, is only symptomatic of that kind of hysterics which an angry lady sometimes indulges in when she cannot have her own way. The best cure for that sort of thing is the good old plan of taking no notice. We have every confidence that the Selecting Committee will not pass over any work which has a reasonable claim to acceptance. At one time or another we have engaged in exhibition work of various kinds with all the members of the Committee who collectively may be relied upon to bring to their task an amount of acumen, clear common sense, and non-partisanship which is the best equipment for their functions. It may not be an ideal Committee. Combinations of the kind are not easily to be had, and, if they are scarce at Pall Mall, we must be allowed to say, deliberately, that they are no more plentiful in Piccadilly. We assure our readers near and far that this year's Selecting Committee of the R.P.S. Exhibition is, on the whole, well qualified for its work. Exception may be taken to individual members of it, but collectively they are tolerably certain to exercise their function of selection with an intelligence and catholicity of judgment which are not always discernible in persons with higher pretensions to rank as judges of pictorial photography.

\* \* \*

We have received the prospectus and time-table of the Bolt Court Technical School, 6, Bolt-court, Fleet-street, E.C. The first term of the fifth session commences on Monday, October 2 next. The Director of the school is Mr. Charles W. Gamble, and in the prospectus before us full information is given as to fees, hours, and days of classes, and in other respects all other necessary details are specified for the guidance of those desirous of taking advantage of the London County Council's effort to provide the fullest facilities for a practical study of photo-mechanical work. The "process" portion of the syllabus deals exhaustively with the various branches of tone and line work, collotype, and colour (photogravure excepted). We recommend those interested to apply at the address of the school, given above, for a copy of the prospectus.

\* \* \*

FROM General Lloyd, an ardent stereoscopic worker, we have received a print from a decidedly curious and uncommon binocular negative. It is a stereoscopic print of lightning, taken during an electrical storm at Tunbridge Wells in August last. Viewed in the stereoscope, the ribbon-like flash stands out in perfect, if slight, relief, thus showing that the discharge could not have been at a very great distance from the camera, which was fitted with a pair of lenses separated at the usual distance of about three inches. It is the first binocular photograph of such a subject that has come into our possession, and is obviously a most interesting specimen.

\* \* \*

His many friends in all parts of the world will be sorry to learn that Mr. A. L. Henderson has been somewhat seriously ill with a prostrate trouble. For more than two months past he has been unable to follow up his photographic work. At the present moment he is an inmate of a nursing home at the West-end of London, and it is hoped that the best of attention and the highest surgical skill will shortly restore him to per-

fect health. In the mean time Mr. Henderson is assured of widespread sympathy at being placed temporarily *hors de combat*, and the knowledge that everybody will rejoice to see him about again, well and strong and full of his usual energy and enthusiasm.

\* \* \*

In the days that are gone Miall's gelatine dry plates deservedly held a high place in the estimation of the photographic public. They occupied the market from about 1878 till 1886, and we hear them well spoken of by good judges even to this day. Since the year last named Mr. Frank Miall has devoted himself to photographic cabinet work, but he has now decided to return to the manufacture of gelatine dry plates. Mr. Miall, whose address is 13, Shelgate-road, Clapham Junction, S.W., has only to turn out plates as good as those to which he accustomed the public fourteen or fifteen years ago to reap success at the hands of a new generation of photographers.

#### CURIOSITIES OF LIGHT AND SIGHT.

In the phenomena of light and vision no class of persons can have a deeper interest than photographers. The whole superstructure of photography is built upon the properties of light in affecting sensitive compounds of silver, but the manner in which light acts in the formation of the photographic image, as well as the exact way in which the haloid salts are affected by the impact of the spectrum rays, are still so far from being thoroughly understood, that the entire subject is surrounded by an amount of mystery which in its fascination appeals alike to the imagination and the speculatively experimental researches of the inquiring student. Light, moreover, has to be considered not merely as a form of energy which is probably electrical in its origin, if not in its nature, but as the prime source of all the engaging marvels of the subjective phenomena of colour, and thus a further interest attaches to its study. In other words, light and colour, physically considered, are one and the same thing, and a close examination of one or the other can scarcely be carried out on independent lines. There is no light without colour, or colour without light—an elementary fact which, we fear, is not grasped by any but a small proportion of modern photographers.

To the scarce literature of this interesting subject, a useful addition has recently been made by Mr. Shelford Bidwell, M.A., F.R.S.,\* and we have no hesitation in recommending the book as an extremely valuable one for the library of the photographer who makes a study of the physics of his subject a matter of paramount concern. Mr. Bidwell is to lecture at the Camera Club on the 26th, on a portion of the subject with which the book under notice proceeds to deal, viz., "Illusions and Anomalies of Vision," and we have no doubt at all that he will rivet the attention of his hearers as firmly as he has done that of the larger public, to which our contemporary, *Nature*, appeals, and in the columns of which classic publication Mr. Bidwell has for years past discoursed with a lucidity not too common amongst scientific writers upon his favourite themes.

Meanwhile, let us lay bare the salient points of a book into

\* *Curiosities of Light and Sight*, by Shelford Bidwell, M.A., LL.B., F.R.S., with 50 illustrations. 226 pp. London: Swan Sonnenschein & Co., Ltd., Paternoster-square.

which we have dipped with rare pleasure. Founded upon lectures which the author has delivered before various societies, the book has an easy conversational charm of style which, though constituting it extremely simple and pleasant reading, nevertheless, leaves you at the end of its perusal satisfied at having had several valuable lessons in physics presented to you in a readily comprehensible form. The opening chapter outlines the undulatory theory of light by the aid of many homely similes, and what is meant by wave-lengths could not be expounded in a clearer fashion. Wave-lengths "differ from one another only as the billows of the Atlantic differ from the ripples on the surface of a pond." Here we have the long and the short of the matter put with inimitable conciseness. In the same chapter the optics of that imperfect optical instrument, the eye, are dealt with in a similarly lucid way, although the author falls into a common mistake of saying that the eye bears a close resemblance to a photographic camera (? and lens) in the formation of an image. Both systems, of course, form images of objects situated axially to them; but the photographic lens lacks the cardinal function of "accommodation," and in other respects, as we have elsewhere pointed out, the resemblance between the eye and the photographic lens is not so close as it is popularly supposed to be.

Colour and its perception, which forms the theme of the second chapter, gives the reader a very clear exposition of the Young-Helmholtz theory of colour vision, and, though Mr. Bidwell concludes that "the true fundamental colour sensations, if such really exist at all, cannot yet be regarded as finally settled," we recommend the chapter to the student of three-colour photography as a simple exposition of the principles upon which trichromatic processes are necessarily based. Many curious phenomena are dealt with in succeeding chapters on optical defects of the human eye; optical illusions and curiosities of vision. They all tend to emphasise the fact that the eye is not to be depended upon when it comes to estimate size, shape, distance, or form; its powers of accurate perception are very limited, and are influenced, if not governed, by the imaginativeness of the individual. In other words, what we see and what we think we see are two different things. As to Mr. Bidwell's speculation, that "possibly the human eye is at present in process of transformation from an inferior type to a different and more perfect one," we must point out that the education of the eye forms no part of the modern scholastic curriculum, and that defective vision appears to be on the increase with all classes of the community. We can, nevertheless, heartily recommend Mr. Bidwell's book as full of interesting and suggestive matter on the subjects of light and vision.

It is interesting to speculate as to how human vision would be exercised were the eye, instead of being an admittedly imperfect optical system with the aberrations that commonly characterise it—astigmatism, curvature of field, and spherical aberration, to name the three universal defects, adding thereto colour blindness to a greater or less extent—were the eye comparable to a well-corrected modern anastigmatic lens. In such case should we be conscious of seeing better than we do at present? We may assume that in its corrected form the crystalline lens would transmit sharper images of external objects to the brain, and that the mental impression of the colour and definition of what we look at would be acuter than it is at present.

But is an optically perfected eye a necessity? "With all

its anomalies the eye fulfils its proper functions very perfectly," says Mr. Shelford Bidwell; "the more so, perhaps, because it is under the influence and control of the mind. If anything is more remarkable," adds Mr. Bidwell, "then the ease and certainty with which we have learnt to interpret ocular indications when they are in some sort of conformity with external objects, it is the pertinacity with which we refuse to be misled when our eyes are doing their best to deceive us. In our earliest years we began to find out that we must not believe all we saw. Experience gradually taught us that on certain points, and under certain circumstances, the indications of our organs of vision were uniformly meaningless or fallacious, and we soon discovered that it would save us trouble, and add to the comfort of life, if we cultivated a habit of completely ignoring all such visual sensations as were of no practical value. In this most of us have been remarkably successful; so much so, that if from motives of curiosity, or for the sake of scientific experiment, we wish to direct our attention to the sensations in question, and to see things as they actually appear, we can only do so with the greatest difficulty; sometimes, indeed, not at all, unless with the assistance of some specially contrived artifice."

The little book is full of equally suggestive points on the phenomena of light and vision, and we can cordially recommend it to our readers. We have not space to give more than a few indications of the nature of its fascinating contents.

---

**Cathode Rays.**—In a paper in *Wiedemann's Annalen*, Herr A. Wehnelt, the inventor of the electrolytic break, which promises almost to revolutionise the practice of Röntgen-ray work, gives the result of his recent experiment with cathode rays. There is always a certain amount of lack of sharpness in these skiographs; but, seeing that they are virtually simply the result of shadows of opaque objects, this is necessarily inseparable from linear radiations whose focus is not a point. However, Herr Wehnelt's results may help in this direction. He differentiates the rays into two classes: "one produced by rays emerging from the cathode normal to its surface, and crossing each other at a focus in the case of a curved cathode; the other consisting always of upright shadows thrown by rays travelling in a direction parallel to the axis of the tube." Our extract is from the columns of *Nature*, and tends to a little confusion of idea, possibly through the medium of translation.

---

**Improved Optical Conditions in Photo-micrography.**—At a recent meeting of the Royal Society of Edinburgh Mr. W. Forgan exhibited his practical method of enlarging and deepening the field of a compound microscope. We have no practical acquaintance with his method; but, if actual practice should bear out the claims advanced, it would amount almost to a revolution in optical conditions. The essence of the new plan consists in shortening the distance between the object-glass and the eye-piece, and thus enlarging the field, though reducing the amount of enlargement, the optical arrangement, to a certain extent, resembling that of a telescope. It was stated that the depth of focus obtained was remarkable. The main question to be answered is, Is the depth of focus greater than would be obtained with the use of an objective of longer focus and the normal length of tube, for it is evident that, *ceteris paribus*, the longer the equivalent focus of an objective the greater the distance between the planes between which objects are virtually in focus?

---

**Ammoniacal Nitrate of Silver.**—The use of this salt dates back to some of the earliest days of photographic practice.

though one hears little of it nowadays, the usual conditions in printing processes, for example, being just the opposite to those obtained with the use of such a bath in sensitising albumenised paper. Yet we have obtained results with albumenised paper surpassing what we could obtain by any other method. The great drawback to the plan is the liability of the paper to yellow in so much shorter a space of time than when the paper is sensitised on a neutral bath, not to speak of the after-use of citric acid. Our plan was to divide the solution of silver into two parts, add ammonia to one until the precipitate was just redissolved, and then to add the second moiety of silver solution and redissolve the new precipitate by the cautious addition of nitric acid. MM. Berthelot and Delépine lately presented to the Paris Academy of Sciences an account of their investigation upon ammoniacal nitrate of silver, and they find it to consist in reality of the nitrate of a complex stable ammoniated base forming two stable salts in solution. This base is as powerful as the mineral alkalies.

**A Bull Fight in a Church.**—We have often referred to the use that the Rev. W. Carlile, of St. Mary-at-Hill Church, Monument, makes of the lantern at his Sunday-evening services, and how it is appreciated by those who attend; but the subjects dealt with have been of a rather different character from that announced for Sunday last, which was, "Boulogne Bull Fights," with limelight illustrations, and probably it attracted a good attendance. No doubt, this subject, with the pictures, was chosen as an object-lesson to teach a moral and to attract a congregation, but, to say the least of it, was a little sensational. If illustrations of a bull fight, with all its revolting details, why not those of a prize fight? It would be sure to attract, and many who attended might, doubtless, heed the moral. Some, however, will probably consider that lantern illustrations of bull fights are better suited for music halls than for a church, notwithstanding the moral to be taught.

**Dangerous Photography.**—Photographers frequently run dangerous risks in the pursuit of their art. It comes to us that an amateur, forming one of a picnic party, who was arranging his camera at Jackdaw Crag, Boston Spa, slipped and fell a distance of 100 feet, with the result that he is now lying in the infirmary suffering from concussion of the brain. We have often seen photographers, engrossed in their work, running very great risks, shifting the camera from place to place in order to get the best view, heedless for the time of what may be behind them. We even confess to having done the same thing ourselves and narrowly escaped an accident. Photographers should be very cautious, when working in precipitous places, not to forget, while they are absorbed in their work, that they are on dangerous ground while moving the camera from place to place. We call special attention to this matter, as many are now taking their holidays on photography bent.

**Confiscated Cinematograph Films.**—According to a weekly lay contemporary, the films for a series of "living pictures" of the Dreyfus court martial, which were intended for the Empire Theatre, South Shields, have been confiscated by the French Government. If this be true, it is difficult to conceive for what reason. Photography by means of "living pictures" could show nothing that the French Government need be ashamed of, one would think. The case might possibly be different if the living pictures could depict what was said, and the way it was said, by some of the Army witnesses in the case—some of the generals, for example. Perhaps, however, it is as well that the films were confiscated, judging from what took place at some of the music halls on Saturday night when the verdict was known, and reference made to it during the performances. It is not well that photography should be made the means of holding up our neighbours' internal affairs to ridicule.

#### KEW OBSERVATORY AND THE NATIONAL PHYSICAL LABORATORY.

TWELVE thousand pounds to cover initial expenditure in buildings, and a further annual subvention of 4000*l.* a year, has been voted for the establishment of the new Physical Laboratory, and, as the governing body of Kew Observatory are willing to become merged in it, and will thus bring into the funds 458*l.* per annum from the Gassiot Trust, with a certainty of at least 2700*l.* per annum from standardising fees, the institution will start with every prospect of success. It may be remembered that the purposes of the new body are stated in the accepted recommendation of the Committee appointed by the Treasury, Lord Rayleigh being Chairman; they are, "the establishment of a public institution for standardising and verifying instruments, for testing materials, and for the determination of constants. The work of the Kew Observatory in this direction is perhaps best known by its verifications of thermometers, though one might expect that, among photographers at least, its testing of lenses might be most familiar; but, as a matter of fact, the number of photographic lenses sent to Kew is decidedly disappointing. It is true that the modern anastigmatic type of lens, being at present in the hands of a few makers only, and they of the very first rank, renders a Kew certificate almost useless; but there are still an immense number of single lenses, and lenses of the rectilinear or "symmetrical" type, and those only who have had such pass through their hands know the vast difference that exists between the instruments of various makers. As a sign of the time, we notice one maker to the trade publishes a separate list of rectilinear lenses which he guarantees to pass the Kew examination, which, indeed, he offers to have carried out on any lens purchased under this list.

#### PHOTOGRAPHY IN LEGAL CASES.

MORE than once we have alluded to the use to which photography has been put in the celebrated Dreyfus case, and, we are sorry to say, according to the newspaper reports, not in the interests of truth and justice. We have, most of us, read of the evidence given by Bertillon, an official photographer and pseudo expert in handwriting, and his absurd theories. But in this case it seems that our art was only invoked to prove, or, in the opinion of most people in this country, to endeavour to prove the guilt of the unfortunate man Dreyfus, and not to promote justice. Such uses are more or less a libel on photography. In cases where disputed handwriting or signatures are in question, it would be best to show photographic enlargements, on a large scale, of the documents supposed fictitious and genuine.

The lantern has been suggested for the purpose, but in law courts a darkened room is not available, and, even if it were, it would not be so good as enlarged facsimiles on paper, inasmuch as with the lantern only one reproduction could be seen at a time, whereas with enlargements several could be placed before the Court, the judge, and the jury, while the experts in handwriting, *pro* and *con*, could explain the similarity or dissimilarity of the writing in the disputed documents, while the Court had the comparative reproductions before them. Some short time back we had the opportunity of seeing, *sub rosa*, some enlargements of documents—admittedly genuine and one alleged fraudulent. The originals were about six inches long, and they were enlarged to something like five feet, and separate enlargements were made of the signatures themselves to much larger dimensions. The result was that the case never came into Court at all, the enlarged photographs settled the case. Handwriting experts' evidence is generally discounted in law cases, but when enlargements of signatures, say, from two inches to thirty or forty inches, are before it, the Court can then generally form its own opinion, particularly when assisted by the experts engaged by the different disputants. Bromide enlargements are quickly and comparatively cheaply made, and are well suited for the purpose.

#### THE METRIC SYSTEM AGAIN.

THERE is no question that, sooner or later, the metric system of weights and measures must be adopted in this country. At the Conference of the Associated Chambers of Commerce at Belfast last week, under the presidency of Sir Stafford Northcote, M.P., no less than five resolutions relating to the metric system appeared on the agenda. These were from Birmingham, London, Bristol, and Leicester Chambers; but, with the acquiescence of the delegates, only one motion, covering the whole ques-

tion, was proposed. It was to this effect, that the Association again affirms that the metric system of weights and measures should be made compulsory in the United Kingdom, and strongly advises Her Majesty's Government to use it in all Government departments. The resolution was adopted, with an addition to the effect that each trade organization should be asked to use its influence with the School Boards within its district to have the system properly taught, as now authorised in the Code.

The present system, as used in this country and in America, is open to many objections, and the metric is not free from some; but it would be a great advantage to trading interests if there were uniformity throughout the world. As the metric system is more largely used all through the world, it is not likely that that will be changed, and as it is only in Britain and America that our system is in vogue, it would seem that it is we who should make the alteration for the sake of uniformity. We are glad to see that many photographic manufacturers—plate-makers, for example—are now issuing their formulae under both systems. Universal uniformity alike, both in weights, measures, and scales, is most desirable. Take, for example, thermometer scales; three are in use on some parts of the Continent. In France, for example, the Centigrade, with  $100^\circ$  between the freezing and boiling points of water; in Germany the Réaumur, with  $80^\circ$  between the freezing and boiling points; here and in America the Fahrenheit, in which the difference between these points is  $180^\circ$ . In the two former the zero is the freezing point of water; in the last-named it is  $32^\circ$  below that. This shows the confusion that exists in the different thermometer scales. Wherever the metric system is in vogue the barometer scale is quoted in millimetres; here it is in inches. This would, of course, be remedied if the metric system were adopted here.

#### THE ORIGIN AND HISTORY OF CERTAIN TRIPLE ANASTIGMATS.\*

EMIL VON HOËGH attributed the fact that double objectives, composed of two systems of triple lenses, each being separately corrected, both spherically and astigmatically, have received so much attention during the last few years, to the doubts as to their practicability, which had existed up to that time. The first form† the so-called "double anastigmat" of Goerz, contains two typically different forms of construction. One (fig. 15) consists of a biconcave lens of flint glass of medium refraction (1.57) enclosed between two other lenses, one of lower refraction (1.51) and one of higher refraction (1.61), both positive. In consequence of this peculiarity of construction, two forms are conceivable; in one case the first lens may be the one of lower refraction (fig. 15A), in the other one of higher refraction (fig. 15B). The first form produces a lens spherically and astigmatically corrected, of positive focal length; the second form can only be spherically and astigmatically corrected for a negative focal length. In both cases the spherical error is removed by the first cemented surface (Z—S), and anastigmatic flatness of image is produced by the second (S—Z).

The second form of construction (fig. 16) consists of a positive lens of medium refraction (1.57) enclosed between two negative lenses, one of which is of lower refraction (1.51) and the other of higher refraction (1.61). Here, again, two forms are conceivable, *a* and *b*, of which one (*a*) produces an anastigmat of positive focal length, and the other (*b*) a similar one of negative focal length. Here, in both cases, the first cemented surface (S—Z) corrects the astigmatic error, and the second surface (Z—S) the spherical error.

Soon after the publication of Goerz's patent, Von Hoëgh set himself the problem of discovering whether, among the many conceivable combinations of the triple lens, which include the action of opposite surfaces there were any (besides those already attempted and proved practicable, which could render possible the simultaneous correction of the two errors here illustrated. He came to the conclusion, after a whole course of calculations, that all the combinations which he had tried, with the exception of two, which stood in close relation to those already known, excluded the possibility of eliminating both errors. These two types of objective, regarded purely from the exterior, result directly from those of the double anastigmat if the two lenses, connected by the spherically corrective cemented surface, are subjoined in the inverted order of the third lens. Figs. 17 and 18 show these two forms. In this combination

figs. *a* produce an anastigmat of positive focal length; figs. *b* of negative focal length. The reason of the above-stated fact (viz., that in all other types of the triple lens, especially also in the triple meniscus systems, the obtaining of the correction of the image is impossible) is that the existence of a cemented surface of a positive type, acting simultaneously with a surface of a negative type does not suffice for the correction of this error. These surfaces only produce extension of the image without increasing the astigmatism when they maintain in their system a curve in opposition to the incident light, so that the principal ray strikes the surface at a comparatively large angle, while it is indifferent to the correction of the spherical error at the axis (but at the axis only), which direction the required surface maintains. With respect to these circumstances, the conditions for the simultaneous correction of spherical and astigmatic errors in a triple lens are as follows:—

The presence of a cemented surface acting collectively, and of reacting descriptively, further (*a*) in lenses of positive focal length a biconvex lens of higher refraction, or a biconcave lens of lower refraction; (*b*) in lenses of negative focal length, a biconvex lens of lower refraction, or a biconcave lens of higher refraction. With this, the list of those forms of construction of the triple-lens system, which render possible the elimination of both errors, is exhausted. This is also true of systems formed of four or more lenses, as there is then a corresponding number of cemented surfaces acting in the same way. If we leave out the combinations of negative focal length which have not any great practical value, there remain four constructive forms of the anastigmatic principle among the triple lens combinations. We have not yet treated of the chromatic error. In consequence of the abundance of glass material produced by the Jena Glass Works, this error may be eliminated in all four combinations, as that glass may be selected for one zone at least of the objective aperture. The above-named conditions do not by any means ensure a good photographic objective.

There are always errors in every system in a greater or less degree, which disappear in the double objective, but have great effect on the action of a single objective. The most important errors of this kind are as follows:—

1. The error in the rays of the middle zone, which remains after the elimination of the spherical error of the ray of highest incidence.
2. The chromatic difference of the spherical aberration, i.e., the spherical aberration remaining in the light when it has been removed for the chemical rays, and conversely.
3. The degree of aberration from apochromatism, i.e., the correction of the error of colours for as many colours as possible, an error the correction of which is closely connected with that of two others and depends on the use of flint glass and crown glass, the spectra of which advance in the different regions as nearly proportionately as possible.
4. The deviation from flatness of field in the directions of rays other from those in which, in the ideal field, the two astigmatic points are brought to a junction.
5. The difference, arising in the directions of rays between the centre and edge of the image.

The above-named errors appear in the double objective as well as in the single objective, while the following errors are not perceptible in the double objective on account of the symmetrical adjustment.

6. The amount of deviation from the fulfilment of the one sine condition, i.e., the requirement that, if possible, the cones of all the rays, of whatever height of incidence, shall produce images of equal size from one element of plane in the image field.
7. The chromatic difference of the sine condition.
8. The chromatic difference of the deviation (*Ablenkung*) of the principal ray falling obliquely, or the different size of the image of objects lying side by side in the case of the smallest aperture regarded as a point.
9. The distortion (i.e., the aberration from the point of contact with the plane of the image) of the rays falling parallel to the principal ray in the greatest contrast to the same.

The above-named numerous errors have not been yet considered after the fulfilment of the chief conditions, and it would be an impossible, or, at least, an unlikely, coincidence to find them all corrected simultaneously in any one form of construction. The preference must therefore be given to that form of construction in which the most important errors occur in a small degree only, or are occasionally entirely removed even.

The simultaneous correction of errors Nos. 2 to 5 in the above list, in the form of construction presented in fig. 15, decides the question as to which form is the best to choose, since it was found to be most important to produce a double objective of large aperture answering as many requirements as possible.

\* Continued from p. 551, September 1. Communicated by Philip E. B. Jourdain. The references to figures here (*x*) correspond to figures *x*+3 in Eder's *Jahrbuch*, 1897, pp. 76 and 77.

† D. R.-P., 74,437.

Unlike this, the form in fig. 16 acts unfavourably as a double objective on account of its insufficient powers of correction of errors Nos. 2 and 3, although in the single system it has the advantage that errors Nos. 6 and 9 occur in a substantially slight degree. Nevertheless, this advantage, occurring only in the single lens, by no means equals those just mentioned as belonging to form No. 1. And this same form of the double anastigmat has essential advantages also over the other form in fig. 17. Both forms are pretty much alike in respect to errors Nos. 1 to 3. In the form in fig. 17, on account of the unfavourable position of the dispersive cemented surface (it is placed opposite to the incident light), all the other errors, and especially those in connexion with the single lens, have an essentially disturbing effect. The last form (fig. 18) has not yet been treated of. This would be more impracticable than the third form (fig. 17), and would stand in the same relation to it that the two constructive forms of the double anastigmat do to each other.

In conclusion, Von Höegh "ventured to express his opinion" that, in the forms of double anastigmat, not all indeed, but by far the most favourable, forms of the triple-lens anastigmat have been discovered.

DOROTHEA FEVERIL TURNBULL.

### THE PHOTOGRAPHY OF COLOUR.

[Paper read before the Royal Photographic Society, and published in its Journal.]

THE Photography of Colour, the title of the subject I have the honour of bringing before you this evening, is a wide one, but I propose to speak of only two of its many branches: (1) the representation of a coloured object in a monochrome print and (2) the representation of a coloured object in its natural colours by what is generally known as the three-colour process.

In June last I read a paper here on the translation of colour into monochrome, and in the previous November I reviewed the various then known methods of triple printing. I have no startling new principle to bring before you, but wish rather to describe to you what has been done since then in the matter of improvements and simplification of detail, the adaptations of these methods to commercial ends.

Forty years have passed since colour photography had its birth, and for the last twenty-three years we have had, hidden away in our plates, the power of securing photographic action by all the colours of the visible spectrum, although we did not understand how such action could be controlled so as to ensure a correct result, and the time has now arrived when scientific and commercial enterprise should be ready with the materials for the general practice of photography as a means of correct representation of colour, whether as colour or in a monochrome print.

#### WHAT IS A CORRECT REPRESENTATION IN MONOCHROME?

To deal with the first head of my subject it is necessary to clear the way by defining what I mean by a correct representation of a coloured object in a monochrome print. Think for one moment what we are trying to do. Our coloured object really has two scales of contrasts—contrasts of colour and contrasts of light and shade—but obviously we cannot represent contrasts of colour in black and white, so our work is narrowed down to correctly representing light and shade.

I now have on the screen the spectrum of white light, and also a slide in which I have represented the apparent brightness or luminosity of the various parts of the spectrum to the human eye by varying depths of the light and shade. A perfect photograph of the spectrum should give us, then, a result something like this, but the top transparency in the next slide, which is from a photograph of the spectrum taken on a Cadett ordinary plate, shows us how far away from truth the ordinary photograph really is, as you see nearly all the action has taken place in the blue and invisible violet, the highest luminosity of the spectrum, i.e., in the yellow being represented as black. The photograph below it is of the same spectrum, taken at the same time on the Cadett rapid spectrum plate. Here the result is a little better, but still far away from our copy.

It is clear from these facts that what we have to do is to secure such photographic action upon our plates as will give us densities in our negatives directly proportional to the visual intensities of the light reflected from the object, ignoring altogether the colours of the object, no matter what they may be.

We have seen what the perfect result should be like and the result of the best plate we have without a filter, and our inquiry is now narrowed down to finding out how to cut out the action of the invisible violet, and subdue the action of the blue and green, so as to bring the visual and photographic impressions into harmony.

#### ABNEY'S COLOUR SENSITOMETER.

The correct representation of colour, according to luminosity, has been the dream of all lovers of photography for very many years, but the practical difficulties in the commercial production of plates and correct light filters were so great that it is only during the last two months that the photographic public have been enabled to obtain, in a commercial

sense, the necessary materials for this purpose, that is to say, a plate and screen correctly adjusted to each other.

This result has been brought about by Captain Abney's invention of the colour sensitometer. Before this invention the few of us who made approximately perfect colour filters had to photograph the spectrum through various media, and then measure the light transmitted through the various parts of the spectrum negative. For each trial negative we had to go through the measurements again, and the method was very tedious and required far too much time to be practical from a commercial point of view.

Captain Abney's invention has altered the case, and by its means quite as accurate, if not more accurate, results can be obtained, and yet the light can be sold at a reasonable price commercially.

The principle of the sensitometer is this: we take, say, four coloured glasses, which cut the spectrum into fairly definite portions—a red, a yellow, a green, and a blue—and also a white glass, and accurately measure the luminosity of the light coming through those glasses in relation to white light, then reduce the light coming through the glasses to a common luminosity, i.e., that of the darkest of the series, by means of a sector with varying apertures arranged to rotate between the glasses and the source of light; then, provided the glasses are illuminated by exactly the same quality of light as that in which their luminosities were measured, a negative taken through a perfect light filter should represent all five patches by deposits of equal density.

Obviously by this method we can test a number of filters in a very short time when once we have the apparatus correctly set up, and, by means of a repeating back, a dozen exposures can be made on one plate and developed together, a glance at the negative showing us the amount of success obtained.

The very greatest care must necessarily be taken in the construction of the apparatus and in the measurements of the luminosities of the glasses in the first instance, as upon these measurements the accuracy of every filter depends.

#### MEASUREMENT OF LUMINOSITIES.

We had to devise the most perfect apparatus we could for measuring the luminosities, and this apparatus was shown and fully described at the Camera Club lately by Mr. James Cadett. The actual test glasses were selected with every care from fired glasses, so as to ensure the greatest purity consistent with high luminosity and permanency, and the measurements used as a basis for computing the relative apertures of the sector were the means of a large number of separate estimations. I should observe that the measurements are made by varying the aperture of a pair of sectors whilst rotating at 4000 revolutions a minute, and, as the apertures of the sectors cannot be read until the motor has been stopped, it is impossible for the observer to be prejudiced in his estimates by previous readings.

To show how consistent these repeated measurements were, I append a table of some of the measurements of three of the glasses used:—

Red.	Green.	Blue.
$9\frac{8}{10}$ .....	20 .....	$2\frac{1}{2}$
$9\frac{9}{10}$ .....	20 .....	$2\frac{1}{2}$
$9\frac{10}{10}$ .....	20 .....	$2\frac{1}{2}$
10 .....	20 .....	$2\frac{1}{2}$
$9\frac{11}{10}$ .....	20 .....	$2\frac{1}{2}$
$9\frac{12}{10}$ .....	20 $\frac{1}{2}$ .....	$2\frac{1}{2}$
$9\frac{13}{10}$ .....	20 .....	$2\frac{1}{2}$
	20 .....	
	21 .....	
	20 .....	

White being 100.

I should say that all the measurements were by the crater of direct current electric arc light, and the same lamp and current were used in the final test of every filter.

#### FILTERS.

Having the apparatus in perfect order, we set to work on the filters, and, after a considerable amount of experimental work, succeeded in getting all the patches of equal density.

Then, and not till then, we tried the filter and plate on an object in the camera; our first attempt was on this colour chart which, with prints from the resulting negative, I will pass round. I will also pass round the result from the same copy on the Cadett ordinary plate, without the screen.

I should like to make a remark or two about some curiosities of the actual manufacture. The screen consists of four components, two films of coloured gelatine coated on worked glass, and two collodion films, the whole being cemented together in optical contact with Canada balsam. Naturally every care is taken to get each film as nearly the correct tint of colour as possible, but, with every care, the visual test is of very little value. The film is cutting out what the eye does not see, and many of the most perfect filters vary considerably to the eye, whilst of a batch of ten filters which, to the eye, appear all exactly alike, perhaps four or five will be too far out to pass.

Some critics have remarked that, even if we did succeed in getting the correct translation of colour directly proportional to luminosity, we should

not be able to satisfy the artist in the matter of copying paintings, because where, say, a red and a green of the same luminosity came together, the photograph would represent them by equal depth of grey. This is true, but it is also a fact that, granted an artist place two colours of exactly the same luminosity side by side—a thing I have never seen in a painting yet—if we purposely alter our filter so as to differentiate between them, we also alter the relations of every other tone in the picture, and probably destroy all its harmony of light and shade.

I should say that the filter increases exposure about twenty times in good studio light and about forty times on open landscape. Some objection has been taken to such an increase in exposure over what we have been used to in what was called orthochromatic photography, but this filter only just does its work for the most rapid plate we have. Of course, if you are satisfied with representing red as black, you may use a very much lighter filter. One I have here only increases exposure about four times with the Cadett plate, and yet has a wonderful effect in improving blue sky in a landscape, but I do not myself approve of such compromise, and, if a perfect result is possible, I want that or nothing.

#### TRIPLE PRINTING.

I now come to the second branch of my subject, that of triple printing; and, as there are, perhaps, some persons present who are not acquainted with the general principles which underlie this process, you will pardon me if I briefly recapitulate them.

The triple printing process is based upon the fact that all the colours of the spectrum, and therefore all the colours of nature, may be counterfeited sufficiently nearly to deceive the human eye by mixtures of three colours of the spectrum itself, a particular red, green, and blue.

By mixing lights of these three colours we get a close approximation to white light. Taking one of these colours, say red, and placing it before the source of light, you see that a piece of bright blue paper, illuminated by light coming through it, looks black, bright green paper looks almost black, and red paper looks nearly the same as white. Therefore, if we photograph a picture or any object through a red-colour filter, any red object would be represented by full density in the resulting negative, and, of course, every white object would be represented the same. Then, if we take another photograph through a green glass, the green objects will be represented nearly the same as white, and similarly with the blue filter. Therefore, by photographing through filters of these three colours we get the separate colour components of the picture represented by varying densities, white objects being the same in all three.

Three transparencies made from such negatives, and projected in superposition upon a white screen by red, green, and blue-violet coloured lights, will give a representation of the object photographed in its natural colours, as Mr. Ives has shown us in this room several times by means of his kromskop lantern.

#### MEASUREMENT OF COLOUR FILTERS.

Up to this point I have been speaking in a very loose way of taking photographs through red, green, and blue glasses.

Obviously, from what we saw just now with regard to the sensitiveness of the photographic plate with reference to the human eye, some modification of the taking colour filters must be necessary to adapt them to the relative colour sensitiveness of the plate used. Hitherto this alteration has been a matter of trial and error, and, although in skilful hands very good results may be obtained, as the photochromoscope has proved, it is obviously very much more satisfying to work from actual measurements.

It would be commercially impossible to take a number of spectrum photographs with each set of colour filters and measure them, and, from what I have told you with reference to the orthochromatic filters, you will appreciate the total incompetency of the human eye as a test.

Captain Abney has suggested how this actual measurement might be accomplished by a modification of his colour sensitometer, and I want to describe to you how the colour filters which I now hand round have been worked out in accordance with his method, and adjusted for use with the Cadett rapid spectrum plate.

As all the measurements must be made with reference to the reproduction colours, we first of all settle on what these shall be. The first thing to do is to make three standard colour filters, cutting the spectrum into as sharp narrow bands as possible, one in the red, about the line C, another near the line E, and another near the line G, every care being taken to get these as perfect as possible. If the three glasses are cut into the form of sectors of equal dimensions, mounted in a frame, and rapidly rotated in front of a beam of white light, we shall be able to form a very good idea of their suitability for our purpose by comparing the emergent beam with another beam of light from the same source lowered to equal luminosity by a rotating sector.

In my own practice I use a piece of apparatus which divides a beam of light coming from the crater of a direct current electric arc light into four parts. Three of the resulting beams are arranged to overlap on a small square of white plaster, and the fourth beam falls on a similar square close to the first. Each of the three overlapping beams is fitted with one of the standard coloured glasses, and the beams are then adjusted so as to give a white patch. The fourth beam is then reduced

to equal luminosity, so that we have two patches side by side of equal luminosity, one illuminated by the crater of the arc white light, and the other by white light reconstituted from our three reproduction colours.

#### TEST GLASSES.

As we did for the orthochromatic filter, we have now to do with this. Select a set of test glasses to form our sensitometer, say, a good red, an orange, a yellow, chrome green, signal green, a good blue and white glass. We then place one of these glasses in the fourth or normal white light beam, and, by means of a rotating sector in the beams of our reconstituted white light, make a match. All the glasses are measured in this way, and the apertures of the sectors carefully recorded.

Having got these measurements, all that we have to do is to mount the glasses in a row, and then work out three sectors, one for the red, one for the green, and one for the blue filter, in such a manner that each sector shall reduce the luminosity of the particular colour—red, green, or blue—to the luminosity of the lowest luminosity of that colour in the series of glasses.

The test glasses are mounted in a box containing the shaft for the rotating sectors, and the sector for all three colours filter red, green and blue are interchangeable on the shaft, so as to ensure the condition of illumination being the same for all.

Having such an apparatus set up and illuminated by the crater of the electric arc light similar to that used for making the measurements, all that remains to be done is to make each colour filter of such coloured media that, when used with its proper sector, all the test glasses shall be represented in a negative by deposits of equal density.

One precaution must, however, be observed, the exposure given must be short, well within what Messrs. Hurter & Driffield call the straight-line period of exposure for the particular batch of emulsion used, as, with the least over-exposure, all the images of the colour patches even up in a very surprising manner, and a very bad filter might, on such a test, be considered good enough to pass.

Our next slide illustrates the selective action of the three-colour filters. The first vertical row shows actual colour patches of red, green, greenish-blue, and yellow glasses, and side by side I have mounted actual negatives of this row of glasses taken through red, green, and blue colour filters upon the Cadett rapid spectrum plate.

#### PRINTING IN INKS.

Now, if we print from these three negatives in superposition in pure red, green, and blue, such as used by Mr. Ives in his projection experiments, we should not get a facsimile of our copy, for, instead of adding coloured light to coloured light, our second and third impressions laid over the first would cut out what the first passed, and the result would be not white, but black. Therefore, in order to print either as superimposed film lantern slides in colliotype or from type printing blocks, it is necessary to print in inks not of the pure spectrum colours, but in their complementaries, that is to say, in pigments passing two of the three colours we used to form our reconstituted white light, and absorbing the third. The primary colours for pigment printing, therefore, are not red, green, and blue, but greenish-blue, pink, or bluish-red, and yellow, or, as Captain Abney describes them, red, green, blue.

I have here three long slides, graded from one end, which is white, to the other in full strength of these three colours, and I will show you in the lantern how, by various combinations, we can reproduce every tint and shade of colour.

If we take these three negatives through our red, green, and blue filters respectively, and print from them in these three colours, we shall get a facsimile of the object photographed. I will now show you upon the screen three prints of a Japanese fan separately. They look very harsh and crude, but, as we superpose them, you see we get a representation of the object in its natural colours, with all its semi tints and light and shade correctly rendered.

I next show you a three-colour print, which I value very highly, as it was made by Mr. F. E. Ives nearly five years ago; then follow some slides by Mr. Saville Kent, who is well known for the excellent work he has done in many branches of photography, and more especially for the work he did on the Great Barrier Reef in Australia in connexion with corals and biological subjects. He has lately been experimenting with this three-colour transparent pigment process for lantern-slide work, and I am very pleased to be able to show you a few of his beautiful results.

We not only want to print in colours, but in these days we want to print rapidly and in enormous numbers; to this end we must print on the typographic press, and it is the application of the three-colour printing process to type printing that we want to see more successfully worked.

The practical difficulties of obtaining correct colour filters and inks, and the further difficulty of obtaining anything like a faithful copy of the transparencies by the present half-tone block-making process, have kept back development very much; but, now that we have filters, plates, and inks which will produce good results, I think it is probable that within a very short time we shall see a great increase in the use of the process.

## REGISTRATION OF PRINTS.

It would take too long for me to pass through the lantern a set of slides tracing the production of a triple print, but I have had such a set mounted in a frame, and I will hand it round. It comprises the negatives taken through the colour filters, the transparencies printed in the manner of ordinary lantern slides, the three half-tone negatives made from the transparencies with the line screen crossed at particular angles in order to avoid offensive geometric patterns, the prints from the etched plates in yellow, pink, and greenish-blue ink, and the final result of similar impressions in superposition. The transparent triple-film print from the same negative is considerably more perfect than the paper print, for in the latter we have the ill effects and loss of detail caused by the cross-line screen, and it is, further, unfortunately impossible with the crossed-line screen process to represent a scale of tints accurately; that is to say, there are always two places in the scale of the half-tone where the scale of gradation "jumps," and these two "jumps" will always mar the result. Having got the screens and printing inks to come fairly close together, we must set to work and see if we cannot find some means of overcoming these two "jumps" in the block-making process; once we have succeeded in doing that, I think there will be very little difficulty in producing accurate reproductions by means of this type-printing process, with very little work in the way of fine etching.

It is, of course, absolutely necessary that the three prints should be printed in register, and that is one difficulty which we have to overcome. Quite recently a press has been brought to this country which will print all three impressions at one printing. The principle is this: the three blocks are mounted on a cylinder, and as the cylinder revolves the separate half-tone blocks are inked with their respective inks; the rollers are kept just a trifle away from the cylinder, and as each block comes under its correct roller there is a depression in the edge of the cylinder which allows the printing roller to get on to the block and ink it. As the cylinder travels round, the three blocks are inked with their respective inks, but, instead of their being printed directly on to the paper, the colour from the block is transferred to elastic rollers, which deposit their respective impressions one over another upon a metal plate, and, as the blocks can be adjusted by micrometer screws, absolute register can be ensured. When each roller has deposited its respective coloured image on to the metal plate, the paper comes into contact with the plate and picks up all three inks at once, so that the paper only comes in contact with the printing surface once instead of three times. The whole of the three inks are thus transferred at the same moment, and there is therefore no trouble with the expansion and contraction of the paper, buckling at the edges, or the other difficulties that we have to contend with in printing the separate impressions at different times; indeed, if necessary, the impression might be taken on tissue paper, and still be in perfect register.

## LINE SCREENS.

Another difficulty which we have in printing in a type press arises in connexion with the line screens. A half-tone screen consists of crossed lines, and, if we place another screen on top of it at a small angle, we get a watermark pattern, such as I now show you on the screen, and it is only when the screens are at particular angles that we get a pattern which is not offensive. It is therefore necessary that the three blocks should have the screens crossed at particular angles. If we arranged the screens at such an angle as would give the effect we want, a screen which should be large enough for a  $15 \times 12$  picture could only be used for a  $9 \times 7$ , and, in order to print a  $15 \times 12$  picture, we should require a cross-line screen 19 inches square. Mr. Levy has recently introduced some new screens which get over the difficulty in this way: he rules two screens on glasses of the same thickness, one ruled with lines parallel to the two sides, and the other ruled with lines at  $60^\circ$  and  $120^\circ$  to the sides; then the block from the blue transparency is taken on the first screen, and the block from the red transparency through the other screen, and then, by taking the screen from its holder and turning it round, we can get the third negative with the angle of the lines in the opposite direction.

In this way, with two  $15 \times 12$  screens, we can make  $15 \times 12$  negatives, and there is no necessity for the old trick of having a big revolving copying board to hold the transparencies in order to get these crossing angles.

I have one other convenient piece of apparatus to show—a frame for holding the screens in the camera which has been made for me by Messrs. Penrose.

The spectrum plate is of extreme rapidity, and sensitive to nearly all the range of the visible spectrum, and some people have on this account found it a rather difficult plate to work with ordinary dark-room illumination. I showed last June how that difficulty could be got over by the use of three dyed films, and Messrs. Cadett have followed out that suggestion, and have put on the market a safe light for their plate, a specimen of which I have brought for examination.

There is only one other subject that I wish to mention, and that is the paper for half-tone printing. At the present time we are compelled to use the baryta-coated paper, which very much detracts from the charm of the result. I have lately heard of some experiments in the production of a rag-made paper, with a system of calendering rollers,

which will give results nearly as good as baryta paper, and upon which I believe a little further experiment will enable us to produce prints quite equal to those on the heavily loaded papers of the present time. In the course of a few years, books printed on sulphate-loaded papers will drop to pieces, and it is very unfortunate that our work should be lost in that way. I therefore hope that every endeavour will be made to provide papers upon which our pictures may be printed with some chance of permanency.

E. SANGER SHEPHERD.

## KACHIN.

At the meeting of the London and Provincial Photographic Association, on September 7, Messrs. J. J. Griffin's representative attended to demonstrate and describe the new Kachin developer, which, he said, was one of the benzene derivatives. Apart from its value as a photographic developer, pure and simple, Kachin calls for attention on account of its singular property, compounded with a suitable quantity of hyposulphite of soda, of developing and fixing the photographic image concurrently. Hyposulphite of soda in small traces, however, has not been found to affect the developing properties of Kachin to any noticeable extent, and this fact was commended to certain careless amateurs, who frequently get small quantities of hypo in their other solutions with disastrous results, as a point in favour of the new developer.

The distinctive characteristics and claims put forward on behalf of Kachin are briefly as follow: It evolves all detail, being more energetic than any known developer, but the resulting negatives are perfectly clear and without veil or fog. Extreme softness or contrast may be produced at will. Its developing power is not influenced by admixture with hyposulphite of soda, and by combining the processes of developing and fixing the most brilliant results are secured, making the method a unique remedy for over-exposure and giving greater play in exposure. For some time, it was stated, the makers found difficulty in arriving at a formula which would work with sufficient speed, but finally, by the employment of sodium phosphate, the operation of development was rendered much quicker. The precise action of the sodium phosphate in the developing solution is not quite understood at the present time, but it is sufficient to say, continued the demonstrator, that its presence adds to the speed of the development without producing any different effect in the final result. Other advantages claimed for Kachin are that it is easily soluble in water and is not influenced by temperature. Its use is not accompanied by any staining of the hands or the plates, nor does it have any effect upon the skin. It is very economical, the solutions may be used again and again, and it provides a developer very well suited for the treatment of stale plates. The demonstrator passed round results upon a certain brand of plates two years old, comparing metal with Kachin on similar exposures. Attention was further drawn to the fact that none of the formulae for Kachin included bromide of potassium. Originally it was thought that the new developer was very sensitive to the action of this salt, but it is now stated that the addition of a few drops of a ten per cent. solution, besides imparting to the image a little more vigour, does not prolong development to a very great extent. For over-exposures up to as much as fifty drops of the ten per cent. solution per ounce may be used. Negatives were passed round which had been developed and fixed with a combined solution, and others testifying to the keeping qualities of Kachin. One of these was developed with a fresh solution and the other with some used developer kept in a beaker for two days. A number of other plates were passed round showing the effect of bromide, and comparing with Kachin some of the older developers. Finally, Messrs. Griffin's representative showed the development of some negatives with the new developer.

Mr. Davies said that as a result of his trials he liked Kachin very well as a developer, so much so indeed that he had practically adopted it, not least because it did not stain the skin as did pyro. He went on to say, however, that he had not succeeded very well with the formulae advocated in the instructions, which perhaps might be put down to his carelessness or clumsiness. He disliked the caustic alkali, preferring carbonate of soda. The latter was nicer to handle and, moreover, had one great advantage that it did not induce such frilling as he had noticed in the plates developed that evening, even with several brands of plate. Notwithstanding all this, he had not been troubled by prolonged development. At the outside ten minutes sufficed, even with bromide. He also looked with disfavour upon a method of expressing formulae in not easily comprehended terms, such as was done in the present case. He advocated in preference the ten per cent. system. Kachin kept very well in this form with sodium sulphite. He had failed to detect any advantage from the use of phosphate of soda, and finally said that he appreciated fully the merits of Kachin, but did not like the formula.

Mr. A. Mackie was unable to speak of Kachin from experience, but he supported the suggestion that it should be made up in ten per cent. solutions, so that a ready calculation of the proportion of one ingredient to another might be made. It seemed to him that, whenever new developers were introduced, the makers went out of their way to make the formulae as complicated as possible. He had recently given up pyro for ortol; but, before doing so, he had been compelled to compound his solutions on the same basis as he had previously done for pyro in order

to learn how much of each ingredient was required for a negative of a certain character. The same would apply to Kachin before its comparative value could be ascertained.

Mr. S. H. Fry stated it to be his opinion that a strong reason should always exist for the introduction of new developers. Did he understand that any more cogent reason existed for the adoption of Kachin than that it did not stain the fingers?

The reply given was that Kachin in solution was much more stable than pyro, which had been mentioned. It was understood that the preliminary experiments of the makers had probably been confined to plates of German manufacture, a fact which would account for any modification of formula advisable for users of English plates.

Mr. Fry said the fact that a developer had great keeping qualities appealed to him in a very slight degree. He made his developer to use, not to keep.

The demonstrator pointed out that one had to consider the amateur element in photography. With these it was a common practice to prepare large quantities of solution, and, however long it lasted, it was always expected to give a good account of itself. Taking metol, then, it was well known that that developer would not keep, and he thought that the superior qualities of Kachin in this direction were decidedly one reason for its introduction.

There ensued some discussion on keeping properties, in which that of pyro, hydroquinone, rodinal, and metol was referred to, one member asserting that he had kept the latter well for six months.

Mr. A. Haddon challenged the statement that Kachin was a new developer. Pyro-catechin, which he understood was the same as Kachin, was known more than two years ago. He asked whether it was a necessity to use the caustic alkali with the combined developing and fixing solution, as, if so, he did not think it would ever come into vogue. In some trials he made with a formula published some time back the film in almost every case came away in large pieces through frilling.

It was stated in reply that the makers advocated the use of the caustic alkali, which they considered necessary. The date of the English patent for pyro-catechin was 1891, but before that in Germany. The preparation had not, however, been on the English market. Difficulties in the process of manufacture had to be overcome, and uniform dry crystals were now made.

Replying to a further statement that its developing powers were known long before, it was said that forty years ago it could be obtained in solution; but, though its laboratory production might have been practicable, its commercial preparation and the reduction of the time necessary to a minimum was not arrived at until later.

Mr. Haddon said that he had had a sample in solid form for eighteen years at least, and it was still dry.

### PANORAMIC CAMERAS.

MR. C. SHAW, of Brooklyn, has patented some improvements in panoramic cameras, which are thus described in his specification.

Fig. 1 is a horizontal sectional view of a camera embodying the invention. Fig. 2 is a vertical sectional view of the casing and showing a rear elevation of the camera parts. Fig. 3 is a vertical sectional view. Fig. 4 is a detail cross-sectional view of a lens cylinder and a light shaft. Fig. 5 is a perspective view of the camera.

A represents a suitable casing for containing the several parts of the camera. One of its walls, as, for instance, the wall, A<sup>1</sup>, is detachable from the remainder of the casing, says Mr. Shaw, and it is to this wall that I connect two plates, between which plates several parts of the camera mechanism are located and held. This arrangement permits of the working parts of the camera being removed from the casing for examination and the substituting of one film for another.

B<sup>1</sup> represents the two plates that are connected to the wall, A<sup>1</sup>, and which extend outwardly therefrom. These plates are detachably connected to protruding parts, a, of the wall, A<sup>1</sup>. The parts, a, may be integral with the wall, A<sup>1</sup>, or separate therefrom, in which case they are held by screws, a<sup>1</sup>. Between the two plates, B<sup>1</sup>, and at the sides thereof, I locate walls, b. These walls may be supported by standards, b<sup>1</sup>, to which they are secured, and the standards may be held at their ends between the two plates. These standards also serve to support the plates, B<sup>1</sup>, and to space them apart. The purpose of these walls, b, is to exclude light from that part of the film not within the path of movement of a light shaft that is employed in the camera.

c represents a cylinder placed vertically in an opening provided in the wall, A<sup>1</sup>. It is preferably arranged to have a portion projecting beyond the outer surface of the wall, A<sup>1</sup>. It is arranged to oscillate in the opening on journals that are provided in the ends of the cylinder. These journals may conveniently consist of circular plates, c, that fit in the ends of the cylinder, c. These plates may be carried by the plates, B<sup>1</sup>, being secured thereto by any desired means, as, for example, by solder. The cylinder is provided with an opening, c<sup>1</sup>, in that portion of its wall projecting beyond the wall, A, and diametrically opposite this opening is a second opening, into which one end of the light shaft, c<sup>2</sup>, is secured. The light shaft is preferably rectangular in cross section, and

is adapted to move with the cylinder, and it is of such a length as to have its free end move in a plane that is parallel with and adjacent to the film or other sensitised surface used in the camera.

c<sup>3</sup> represents a lens that is carried by a suitable holder, c<sup>4</sup>. The holder, c<sup>4</sup>, is inserted in an opening provided in a wood or other block, c<sup>5</sup>, that is held within the cylinder, c. The lens is placed in the line of the openings in the cylinder, c, so as to project the light rays through the light shaft on to the sensitised surface. When the cylinder, c, carrying the lens, is oscillated with the lens exposed, the light rays from the different parts of the view being photographed will be projected by the lens through the light shaft on to successive portions of the film or plate in the camera as the light shaft is moved in front thereof. The cylinder may be oscillated in one direction by means of a coiled spring, c<sup>6</sup>, that is preferably located within the cylinder. One end of the spring is secured to a stationary part, as, for example, to a pin, c<sup>7</sup>, carried by one of the plates, c, while the other end of the spring may be secured to the cylinder. The cylinder and light shaft may be moved in the other and opposite direction for the purpose of "setting" the lens and light

shaft by hand. When the cylinder is moved in this direction, the spring is placed under tension to move the cylinder and light shaft in the first-mentioned direction, that is, in the direction to expose the film. It is obvious that the speed of the lens cylinder and light shaft may be regulated by changing the tension of the spring. The joint made by the wall of the cylinder and the walls of the opening in the part, A<sup>1</sup>, in which the cylinder is placed, may be made light-proof in any convenient manner, as by felt, c<sup>8</sup>, or metal, which would conform to the wall of the cylinder. Any desired means may be employed for holding the light shaft and cylinder in "set" position and for releasing them from set position. I have shown in the drawings the following arrangement of parts for doing this. A lever, D, is pivoted to the upper plate, B, so as to have one of its ends, d, in the path of movement of the light shaft. As the light shaft is moved to set position this end, d, will be made to engage with the light shaft to hold it against the action of the spring, c<sup>6</sup>. A flat spring, d<sup>1</sup>, is preferably provided for holding the end, d, in the path of movement of the light shaft. The other end, d<sup>2</sup>, of the lever is so arranged as to be engaged by a button d<sup>3</sup>, carried by the casing, A, which, when depressed to engage the end, d<sup>2</sup>, causes the end, d, to move out of engagement with the light shaft. A shutter, c<sup>8</sup>, may be provided in the cylinder to cover the lens when desired, a knob or projection, c<sup>9</sup>, being provided for moving it over the lens after the film has been exposed and the cylinder and light shaft are to be reset. This knob or projection may also be used to move the cylinder and light shaft to set position.

E<sup>1</sup> represent shutters, which are provided for the end of the light

shaft. One of the shutters is provided for closing the end of the light shaft when the camera is in set position, while the other shutter is for closing the end of the light shaft after it has been released from set position and it has moved in front of the film to expose it. With this arrangement of the shutters for the end of the light shaft all light rays from the lens are excluded from the camera while the light shaft is at rest. These shutters are operated automatically and preferably by the light shaft coming into engagement with them. Each shutter may conveniently consist of an L-shaped piece of metal that is provided with a pivot,  $e$ , at each end, which pivots have a bearing in the plates,  $b$  and  $b^1$ . A spring,  $e^2$ , is provided for each shutter for the purpose of holding it in such position as to be operated by the light shaft. These springs are preferably flat ones, and they are secured at one of their ends to the walls,  $b$ . The operation of these shutters is as follows: When the light shaft and cylinder are moved to set position, the light shaft engages with one arm,  $e^2$ , of the shutter, against which the spring,  $e^2$ , bears, and moves it against the action of the spring so as to bring the other arm,  $e^1$ , of the shutter over the open end of the light shaft to completely close it. When the light shaft is released to expose the film, the end of the light shaft moves away from the arm,  $e^1$ , to throw the light rays on to the film. As it moves in front of the film it comes into engagement with the arm,  $e^2$ , of the shutter,  $e^1$ , and moves this arm to cause the arm,  $e^1$ , of this shutter to completely close the end of the light shaft and thus prevent any more light rays entering the interior of the camera. The shutter,  $e^2$ , is then moved over the lens and the cylinder and light shaft reset for another exposure. After the cylinder and light shaft have been reset the shutter,  $e^2$ , is moved from in front of the lens, thus having the camera ready for another exposure. It will be seen, therefore, that the purpose of the shutter,  $e^2$ , is merely to cover the lens while the camera is being reset and also to protect the lens from dust, &c., when not in use.

A film is preferably used in the camera, and provision is made for inserting in the camera the spool, on which the film is generally wound, and unwinding the film from the spool as it is needed on to a second spool.  $r$  represents the spool carrying the film,  $f$ , and  $r^1$  the spool on to which the film is wound. The spool,  $r^1$ , is provided with the usual ratchet and the pawl engaging therewith, and this spool is turned by the usual key,  $f^2$ , carried by the casing,  $a$ .

The rollers,  $r$  and  $r^1$ , are removably held in spring pieces,  $f^2$ , that may be secured to the plates,  $b$  and  $b^1$ , on the outside thereof by rivets, which rivets are located at the middle of the pieces. These pieces are near the wall,  $a^1$ , of the casing, so that the spools will be in the position shown in the drawings. The film from the spool,  $r$ , is passed over a roller,  $f^6$ , journaled in the plates,  $b$  and  $b^1$ , and preferably against curved flanges,  $f^4$ , that are carried by the said plates, and over a roller,  $f^5$ , to the spool,  $r^1$ . Guide rods,  $f^7$ , may also be provided to prevent the film moving away from the flanges while being transferred from one spool to the other. The usual opening,  $a^2$ , and its coloured covering,  $a^4$ , are provided in the casing,  $a$ , in order that the position of an unexposed part of the film may be gauged through the usual marks or signs provided on the backing of the film.

#### PHOTOGRAPHY FOR JOURNALISTS.

JOURNALISTS are only now awakening to the fact that a knowledge of photography is of the greatest advantage to them in their profession. At one time a journalist who could sketch well was always in demand, now the one that can combine a little sketching with photography and the pen is always sure of obtaining a good livelihood. This is largely due to the public's craving for illustrations and the great advance in the half-tone process, which has practically revolutionised the engraver's art.

Of course there are some things that photography cannot very well illustrate, such as—a story. Here the artist will always take first place on account of the difficulty in arranging the sitters to look natural, and the quantity of expensive accessories it would require. I am told that photography is used for illustrating stories in several American papers, but it cannot be called a success, because they are not arranged artistically. Photography will always give a truthful rendering of any object (providing the photograph is not faked), and is preferable to an artist's drawing, as it contains more detail, and exactly depicts the faces contained in it. Suppose, for instance, an artist is sketching "the funeral of Mr. Gladstone," he will draw the principal figures in correctly on the spot, the other parts are filled in afterwards. Here the beauty of a photograph comes in, as it will truthfully reproduce every head and posture of persons contained in the angle of view of the camera lens.

Photography is seen at its best when illustrating articles (for which there is a great demand); here it has a very great advantage over sketching, as it is more rapid, and instantaneous photographs can be taken which will exactly reproduce the motions, &c., of the object written about. Take, for instance, an article on, say, "Barnum's acrobats;" here the actions of the arms and legs could be correctly caught at any stage. Sketching would not be of very great use, as the motions are so very rapid that the eye is very often deceived, and the exact actions of the different muscles at the various stages could not all be drawn, as the eye could not see them all at once to allow of notes being taken. It is also of the greatest aid in newspaper work for illustrating race meetings, regattas, and any great funerals or other functions.

Of course, in newspaper illustrating, the great thing would be to get prints out in time to have the blocks made before going to press, as it would be no use getting them out late, as all interest, or the greater part of it, would be lost were they reproduced several days after the events happened. To do this, the exposed plates must be developed soon after exposing, and well washed, not fixed. A piece of bromide paper should then be soaked in water, laid on top of the negative (film to film), and squeegeed in contact. It must be placed in a printing frame and exposed to gas or lamp light for a few seconds. It may then be peeled off and developed in the usual way, washed, dried, and packed off to the paper at once, the sooner the better. This method will have no bad effect upon the negatives, providing they are afterwards well washed and fixed. The prints from them will be quite as good as they would be were the negatives fixed, but it must be remembered that the negatives will not keep long unless they are thoroughly fixed.

The best kind of camera for the journalist is, no doubt, a hand camera, as it is easily carried and does not take up much room. It has another advantage, and that is, it is always ready for use and requires no setting up or focussing. There are many suitable hand cameras on the market, and no difficulty will be found in choosing one. It will be best, though, to pay a good price and have a reliable one. On the whole, one with a R.R. lens, fixed focus, with magazine mechanism, taking one dozen plates, will be the most useful. Films are lighter, but more expensive, and not so easily manipulated.

Photographers also can considerably add to their income by sending photographs of any interesting event that happens in their district to the weekly or monthly magazines. Newspapers are also open for the same class of photographs, and will pay handsomely for them. Many magazines will also be pleased to receive pretty photographs of figure studies for frontispieces, &c., from photographers who have had a little artistic training. The payment for these is anything from 7s. 6d. to 1l. 1s. each. Another remunerative branch is to send photographs of any celebrities to the papers as soon as their death has been notified. It is to be greatly deplored that so many amateurs will supply editors with photographs gratuitously, simply for the so-called honour of having them reproduced. They in this way spoil the chances of struggling journalists and photographers.

It would be well if so many of the novelists that use photography in connexion with their plots would first get an insight into it. They would then not make such dastardly mistakes as, for instance, a burglar, breaking into a house in the *dead of night*, accidentally knocks the setting-spring of a camera, with the result that his features become imprinted on the plate, and thus enables the police to capture him.

OSBORN THORNBURY.

#### THE LATE GASTON TISSANDIER.

WE learn from Paris that M. Gaston Tissandier, the famous balloonist and scientific writer, has recently died, after a long illness, in his fifty-sixth year. The deceased aeronaut was born in Paris, and, after having studied chemistry and physics with energy, he took to ballooning with his brother Albert. They made nearly fifty ascents together, four being effected during the siege of Paris by the Germans. They were then attached as balloonists to the Army of the Loire. In 1875 the deceased made the famous ascent in the Zenith balloon, which led to the deaths of his two companions, Croce Spinelli and Swel. They went up a tremendous distance—8600 metres, according to French reckoning—and M. Tissandier showed a marvellous resisting power on the occasion. This fatality did not check his ardour, for he soon afterwards made further ascents with his brother. They notably tried an electric navigable balloon about sixteen years since, and obtained thereby some useful results. M. Gaston Tissandier wrote many important scientific treatises in his time, and was a diligent contributor to reviews on chemical, meteorological, and aeronautic subjects. He and his brother also founded *La Nature*, a most useful periodical for all who are interested in the marvels of sea, sky, and land. One of his latest books was the *Martyrs of Science*, and he has left behind some manuscripts which are of great scientific import and value. To the pages of *La Nature* and other French periodicals M. Tissandier at one time contributed many articles on photographic subjects, several of which in former years were translated and published in these pages.

#### THE CAMERA CLUB.

THE following is the list of papers and other fixtures arranged for the first portion of the Camera Club's forthcoming session:—

OCTOBER, 1899.

Monday, 2.—Opening of Exhibition of Pictures of the East, by Mr. E. R. Ashton.

Thursday, 5, 8.15 p.m.—Mr. E. Sanger Shepherd, "Natural Colour Photography."

Monday, 9, 8.15 p.m.—Mr. Lindsay Johnson, M.A., M.B., &c., "Exhibition of a New Phonograph with Musical Selections."

Wednesday, 11, 8.30 p.m.—Ladies' Evening. Exhibition of Lantern Slides, by members of the Field Club.

Thursday, 12, 8.15 p.m.—Captain W. de W. Abney, C.B., F.R.S., &c., subject to be announced later.

Monday, 16, 8.15 p.m.—Mr. Howard Priestman, "A Climber's Holiday in Lofoten."

Thursday, 19, 8.15 p.m.—Mr. James Cadett, "Cloud and Photographic Landscapes."

Monday, 23, 8.15 p.m.—Lecture, to be announced later.

Thursday, 26, 8.15 p.m.—Mr. Sheldford Bidwell, F.R.S., "Illusions and Anomalies of Vision."

Monday, 30, 8.15 p.m.—Mr. Alfred Watkins, "Some Principles of Development."

#### NOVEMBER.

Thursday, 2, 8.15 p.m.—Mr. T. C. Porter, of Eton College, "Scenery in the Canary Islands."

Monday, 6, 8.30 p.m.—Smoking Concert arranged by Mr. Percy Marshall and Dr. Marshall.

The Club Journal states that important alterations have recently been made in the kitchen department of the Club, which will, it is hoped, lead to a marked improvement in the dining-room.

#### LEEDS CAMERA CLUB'S ANNUAL DINNER.

THE Annual Dinner, which practically opens the winter session of the above Club was held on Wednesday, the 6th inst., at the headquarters of the Club, Grand Restaurant, Boar-lane, Leeds, when about sixty members sat down to dinner, the President (Mr. W. J. Warren) being in the chair, and supported by visitors from the following societies: Mr. W. A. Beevers (President, Huddersfield Photographic Society), Major Norwood (Wakefield), the Rev. W. Curtis (Wakefield), and Mr. R. McKay (of the Leeds Photographic Society), and others.

After an excellent dinner had been done full justice to, the President rose to deliver his presidential address, in the course of which he said: As President of the Leeds Camera Club for the ensuing year, his task was not altogether a bed of roses. It seemed to him that a presidential address should be a general review of photography during the past year, and a few tips as to what they should undertake in the future. He had intended to lay the whole science of photography bare before them, but he suddenly remembered this was an after-dinner speech, and, out of charity and affection for the members of the Club, he had decided not to give this knowledge away. They were opening the session of 1899-1900 with every prospect of success, and they were that day (and he said it with malice aforethought, as the lawyers said) the largest Society in Yorkshire. He hoped that each of them who applauded this remark would realise the fact that it was for this very reason they had the greatest responsibilities of any society in Yorkshire, and every member shared that responsibility. The Committee had been working hard for some time in Leeds for the coming session, and he thought he might congratulate them on having a syllabus which was excelled by no society in the kingdom. Every recognised leader of photography would come and speak to them on the special subject for which such lecturer was specially qualified to speak. Referring to the newly formed Yorkshire Union, he said they had resisted the blandishments of Mr. Clough and the Union, as they would remember, and he thought they had profited by standing out in that respect. They would observe a new feature by endeavouring to make the syllabus and handbook something more than a mere list of lectures, and he trusted they would appreciate this new departure.

It had been suggested that the Club was given over to only one branch of photography—the pictorial side.

It is perfectly true that the leaning of the majority of the members was towards that branch of photography, but at the same time let it be known that one of the most important articles of the belief was this, that without good technical photography, without a thorough knowledge of the science, there could be no successful practice of the art, and he would like once and for all to admit that they who practised pictorial photography had every regard, respect, and appreciation for the scientific side of photography. He would also like to point out that in the Club syllabus the majority of the lectures were of a technical kind, because they recognised that all work, whether scientific or artistic, must be associated with a groundwork of technical excellence, and that a man must learn the nature of his tools, and using them feel no hesitation or impediment about the use of them, before he could do any thorough work.

He wished to emphasise the fact that they were looking to promote the prosperity of the Leeds Camera Club and to gain new members; he was glad to say that some sixteen or eighteen new names had been given in since the issue of the Club's handbook.

He promised them that, if in the future the members would help them by coming to the lectures and doing good work—the best work—that next year they should have a far more startling sensation than they had this year. He had in his mind a vision of club rooms where they might hold meetings and spend their evenings, where they might meet on club

nights and at other times; and all this depended absolutely on themselves. If this session was a success, they would come to them on September 6 next year and invite them to club rooms which would be their own. He concluded by wishing everybody good luck in the new session, and he hoped and trusted that they would help the Committee in it.

After the usual loyal and patriotic toasts Major Norwood (Wakefield) proposed "Success to the Club," coupling with it the names of the President, the Hon. Secretary, and Hon. Treasurer, whose work he remarked on behalf of a club with a membership of 190 was no sinecure.

The Rev. W. Curtis (Wakefield) seconded and the toast was replied to by the President and the Secretary (Mr. John H. Gash), and the Treasurer (Mr. F. Rush), the last-named of whom stated the Club was in a flourishing condition. In asking the Company to drink to the toast of the "Press" the President remarked that he felt personally, and he was sure they would all agree with him in his remarks, that the Press had behaved with the greatest kindness to them. Photography was a technical subject and did not appeal to a vast number of readers, yet they appreciated the fact that the Press had treated them well and had endeavoured in every way to meet them.

Every one was indebted to the Press for the liberal manner in which the lectures were reported, and he had very great pleasure in asking them all to drink to the health of the Press.

## Our Editorial Table.

#### TRAPP'S ALBUMENISED PAPERS.

L. Trapp & Co., 29, Budge-row, E.C.

A SAMPLE of Messrs. Trapp's new brand of ready-sensitised albumenised paper was recently tried by us, and found to yield prints of excellent quality. A good albumen print is hard to beat by any other silver printing-out process, and there will always be many adhering to this method of printing whilst such well-prepared as Messrs. Trapp's is available.

The following baths are recommended for the paper:—

Gold Bath.—To be prepared one hour before use:—

Chloride of gold .....	1 grain.
Acetate of soda (cryst.) .....	24 grains.
Carbonate of soda .....	3 "
Water .....	4 to 5 ounces.

A bath required for immediate use may be prepared as follows:—

Chloride of gold .....	1 grain.
Carbonate of soda .....	10 grains.
Water .....	4 to 5 ounces.

Messrs. Trapp also recommend the use of the following gold bath:—

Chloride of gold .....	1 grain.
Carbonate of soda .....	1½ grains.
Borax .....	30 "
Water .....	3 ounces.

Hypo Bath.—1 ounce of hypo to 10 ounces of water.

#### A MERCURY-IODIDE INTENSIFIER.

Agents: L. Gaumont & Co., 25, Cecil-court, Charing Cross-road, W.C.

MESSRS. LUMIÈRE have recently prepared a mercury-iodide, soda-sulphite intensifier, the uses and properties of which they thus describe:—

The use, as an intensifier, of the well-known solution of mercuric iodide in hyposulphite of soda has not hitherto been general, in spite of the remarkable qualities and facility of employment presented by this intensifier, because of the ultimate change occurring to pictures thus intensified; they turn yellow, after a certain period, which occasions a gradual diminution of the intensity of the negative.

Messrs. Lumière have recognised that the solution of mercuric iodide in anhydrous sulphite of soda, while offering the same advantages as the solution in hyposulphite, presents, to a degree notably less than this latter, the phenomenon of ulterior discolouration of the plate.

This advantage in the use of anhydrous sulphite of soda over hyposulphite springs from the fact that an excess of anhydrous sulphite can be used without disadvantage, while intensification ceases in the presence of an excess of hyposulphite. After determining the cause of alteration and staining of the image, we have arrived at completely avoiding this after-effect, by treating the negative, after intensification, with a developer, which, without changing either the colour or intensity of the image, prevents all the subsequent yellowness, and assures its preservation with the initial colour and intensity. Intensification with mercuric iodide, practised under the conditions which we indicate below, solves, therefore, completely the problem of direct intensification.

This intensifier presents the following qualities: 1. It enables intensification to be effected by the use of a single solution, and the action

to be followed closely on the plate, which is impracticable with the ordinary perchloride of mercury intensifier. 2. The intensification may take place when the plate leaves the fixing bath, after a summary wash, without fear of the yellowing of the film, which would infallibly occur with perchloride of mercury if all trace of hypo were not carefully eliminated. 3. Finally, the bath can be rapidly prepared, its components being very easily soluble.

## COMPOSITION FOR NORMAL INTENSIFIER.

Water .....	100 parts.
Anhydrous sulphite of soda .....	10 "
Mercuric iodide .....	1 part.

The instructions are as follows:—

Dissolve the anhydrous sulphite of soda in the water, then add the mercuric iodide. The solution is almost immediately ready. When it is wished to intensify the plate on leaving the fixing bath, it should be briefly washed and then placed in the intensifying solution. If the intensification is to take place on a negative already dry, it is useless to wet it before plunging it in the intensifier. The action is rapid and very regular, and the gradual intensification can be easily followed by examining it against the light, without fear of stains or discolouration as with perchloride of mercury. The rapid action of the intensifier can be restrained at will without changing the final result by the mere addition of water. On the other hand, the energy of the intensifier can be increased by adding a larger quantity of mercuric iodide, together with anhydrous sulphite of soda, but without exceeding the maximum quantities of 2 grammes of mercuric iodide to 20 grammes of anhydrous sulphite of soda. On leaving the intensifying bath, the plate is briefly washed in running water, then plunged for some minutes in one of the following developers, prepared as for an ordinary development: diamidophenol, para-amidophenol, hydramine, pyrogallie acid, hydroquinone, &c. Under these conditions, without altering the intensity of the negative to any appreciable degree, the after-effects mentioned above are avoided. The operation is finished by washing the plate in running water in the ordinary way.

We hope to have an early opportunity of testing this method of intensification.

## KARAMELLO.

Wholesale Agents: Gear, Chidley & Co., 101, Great Portland-street, N.W.

THIS is a substance manufactured by Johnson's Saccharum Company, of Silvertown, which is put forward as a backing for gelatine dry plates. It is of the consistence of treacle, and has all the appearance of being prepared from a caramel base. We found by practical trial that it is easily applied to the back of the plate in a smooth and even layer, dries quickly, and is readily removable by aqueous solutions. As a safeguard against halation in negatives it answers admirably. Karamello should be popular amongst those who make a point of backing their plates.

## STEREOSCOPIC SLIDES.

Underwood & Underwood, 26, Red Lion-square, W.C.

MESSRS. UNDERWOOD have been good enough to send for our acceptance a set of stereoscopic slides illustrative of scenes in Judea. Accompanying the slides is a little book descriptive of the places photographed. This plan of issuing series of slides in geographically arranged sets should help to make stereoscopy increasingly popular. Some eloquent articles on the beauties of stereography, which were written by the late Dr. Oliver Wendell Holmes, have been reprinted in book form by Messrs. Underwood, and they form a magnificent recommendation of this kind of photography.

## CATALOGUE RECEIVED.

James Bamforth, Station-road, Holmfirth, Yorkshire.

MR. BAMFORTH is the largest producer in Great Britain of life-mode studies, and from the negatives so obtained he prepares lantern slides, a supplementary catalogue of which is now before us. This extends to thirty-two pages, and there are four pages of half-tone reproductions of pictures arranged in Mr. Bamforth's studio. He offers a wide selection of subjects, sacred, humorous, and sentimental, and his catalogue should certainly be obtained by all those interested in entertainments by means of the optical lantern.

## News and Notes.

PHOTOGRAPHIC CLUB.—September 20, at eight o'clock. Discussion, "Uncorrected Lens Work."

THE Optics Committee of the National Physical Research Laboratory consists of the following gentlemen: Lord Rayleigh, Captain Abney, Mr. W. H. M. Christie (Astronomer Royal), Professor Clifton, Mr. T. R. Dallmeyer, Professor Fitzgerald, Professor Joly, Mr. T. Matthews, the Earl of Rosse, and Professor Silvanus Thompson.

A FOURTH edition of Mr. W. Thynne Lynn's *Remarkable Eclipses* has been issued by Mr. E. Stanford, and will be found useful, as it contains information as to forthcoming eclipses, notably the solar eclipse of next year.

"CLAM BAKE."—A correspondent tells us that this is a baking of clams, usually on the seashore. Clams—certain forms of shell fish, bivalves. The bake is a huge fire, a heap, *à la Vesuvius*. The "feed" is understood to be fit for the gods.

STATISTICS obtained by sunshine recorders are interesting. Some curious facts have been recently published by the French Meteorological Bureau at Paris. Spain has 3000 hours of sunshine a year; Italy, 2700; France, 2600; Germany has 1700, while England has but 1400. The average fall of rain in the latter country is greater than in any other European country.

PHOTOGRAPHIC CLASSES AT THE BATTERSEA POLYTECHNIC.—The Committee announce the following photographic classes for photographers, engravers, &c.: A seven months' course of instruction in theoretical and practical photography, on Monday and Thursday evenings, at 7.30, commencing on Monday, September 25, by Mr. E. Senior (Honours Medallist). Particulars of times and fees are given in the prospectus, gratis on application. Detailed prospectus, with syllabus of work, &c., are obtainable for 1d.; post free, 2½d.

"It is a pity that amateur microscopists do not more fully recognise the necessity of recording, to some uniform and convenient scale," says Mr. J. H. Cooke in *Knowledge*, "the dimensions of the microscopic objects that they make their study. This want of uniformity not only detracts from the value of the work done, but it also renders the work of comparison of the drawings of the objects laborious and unreliable. By operating on some objects of known size it is easy to ascertain what arrangement of the microscope, and of its objectives and ocular, is necessary to obtain an image with the camera lucida of any required size. Having determined on a given amplification, it should be adhered to, and a scale be made corresponding to this amplification. The actual dimensions of the object might then be readily ascertained by applying this scale to the various parts of the image or drawing. The value of some such uniform method as this is self-evident."

THE Ludlow Photographic Society's Third Annual Exhibition of Photographic Work will be held in the Assembly Rooms, Ludlow, on Wednesday, October 11. The following is the schedule of classes:—Members' Classes: Class 1.—Set of Three Direct Prints, any size, any process: 1. Landscape or Seascape; 2. Architecture; 3. Figure or Animal Study. Class 2.—Hand Camera. Set of Three Direct Prints, any size, any process, any subject. Class 3.—Lantern Slides. Set of Six. Class 2.—Enlargements. Two Prints of different subjects, enlarged not less than two diameters, any subjects, any process. Direct prints from negatives must be sent with enlargements. Open Classes (for Amateurs): Class 5.—As Class 1 exactly, except that the prints may be direct or enlargements. Class 6.—Hand Camera. Set of Six, any size, any subject. Class 7.—Lantern Slides. Set of Six. Awards in each Class: 1st, silver medal; 2nd, bronze medal. All entries and other communications are to be addressed to the Secretary, Ludlow Photographic Society, 14, Mill-street, Ludlow.

PHRENOLOGY BY PORTRAIT.—A portrait of Dreyfus in a phrenologist's window attracted a great deal of attention early this week. The estimate of his character, based presumably upon a study of the portrait only, is as follows: "A glance will show what a striking correspondence there is between the formation of his (Dreyfus's) head and what is definitely known of his character. Guilty or innocent, his most pronounced characteristics are self-esteem, firmness, approbateness, and the domestic sentiments. It is these that have given him the extraordinary strength of mind that has characterised him during the last five years. Pride and persistence have never left him. With plenty of destructiveness and combativeness, such as gave him a love for things military, he has no small amount of cautiousness and secretiveness. He is a shrewd man, given to thinking much before acting, and well able to keep his own counsel. Strong in love and hate, he is a very human sort of man; not one to make more friends than enemies, but one whose friends will find it hard to disbelieve in him."

THE Committee of the Mid-Cheshire Society of Art, Northwich, announce that the Society's suite of rooms over the Union Bank, Castle Northwich, is now ready. This suite consists of three rooms, two of which will be used for the hanging of oil paintings, water colours, photographs, &c., and for the display of work of art of every description, all being the work of members of the Society. One of the rooms will be provided with literature in connexion with art, including the leading photographic journals. The dark room is fitted up with sink, developing dishes, ruby lamps worked with gas, and an enlarging lantern has been kindly placed at the disposal of the members by one of the Committee. A supply of hypo, both in crystal and solution, is provided, and the Committee hope to be able to always supply this free. The Committee invite members to send in some of their work for the decoration of the rooms, such work can be removed at any time by simply informing the Secretary. The Committee point out the great advantages that are derived from the affiliation of the Society with the Royal Photographic Society of Great Britain, by which lantern slides and materials for about thirty lectures are placed at the disposal of the Society, and a large collection of photographic work of the highest class can be brought down for exhibition at any time. By this affiliation members touring can use the rooms of other affiliated societies in the different towns, we extending the same courtesy in return. Should members wish to photograph places that are not open to the general public for that purpose, the Secretary will do all in his power to obtain the necessary permission. As the Mid-Cheshire Society of Art is now recognised in all photographic circles, both at home and abroad, all notices of competitive exhibitions are sent to the Secretary and are posted up in the rooms. This will enable members to compete for prizes throughout the photographic world. As a case in point, the Secretary has just received from America full particulars of the Philadelphia Salon, to be held in October this year, and to which members are invited to send in work. During the winter months lectures will be given in connexion with various branches of art.

**THE PARIS EXPOSITION.**—The Paris correspondent of the *Daily Telegraph* observes that some prophets of evil having arisen who predict the boycotting of the Universal Exhibition of 1900 by foreign partisans of Captain Dreyfus, and who have even used the phrase, "a commercial Sedan," in connexion with next year's big fair, a writer comes forward in order to show that the Germans, at least, are fully determined to participate to a large extent in the approaching international show. The author of the article has had his facts from the German Commissary of the Exhibition, Herr Richter, who first proclaims to the world that he is in thorough harmony with his French colleagues. Germany, we are told, will be represented in all the groups of the Exhibition except in those of education and colonization. The two departments mentioned have been dispensed with in order to leave more room for artistic and commercial groups. The Art Department will be important, and the two schools will be represented. Herr Anton von Werner is organizing the display for the General Society of German Artists, and the locale of the pictures is to be decorated and arranged by Professor Seidl, of Munich, with the help of Professor von Lembach. Next, perhaps, in interest not commercial will come the German Group No. 18, which has been organized at the wish of the Kaiser, who conferred with the French Ambassador in Berlin, the Marquis de Noailles, on the matter. This is to comprise an historical exhibition of Prussian and German military uniforms from the days of Frederick William, the Grand Elector of Brandenburg, to our own. The scientific, manufacturing, and machinery groups will be very strong, including optical and surgical instruments, chemical laboratories, rare gold and silver work from Hanau and other places, porcelain from the State manufactories, furniture from Berlin and Cologne, toys from Nuremberg and Sonneberg, knick-knacks or brimborions of all sorts made in Germany, silks from Crefeld, lace from Plauen, dynamo machines, cranes, colossal engines, and railway carriages.

ABOUT midnight on Saturdayweek a distressing fatality occurred at Beaumaris, resulting in the loss of the lives of two young men. During the past month, among the numerous yachting parties which at this season of the year make Beaumaris their rendezvous was one consisting of Mr. Norman C. Lange, aged twenty-five, son of Mr. Paul Lange, the well-known amateur photographer, 33, Shrewsbury-road, Oxton; Mr. Thomas W. Frame, aged twenty-four, 25, Mather-road, Birkenhead; and Mr. Ernest Brown, 9, Clementina-terrace, Carlisle, and 65, Fenchurch-street, London. All three apparently were quite well acquainted with the handling of their little craft, a five-rater cruiser, named the *Vixen*, designed by Mr. Lange himself, who is a member of the Royal Liver Yacht Club, and had sailed her during the month all over the Beaumaris and adjoining waters with perfect safety. They had the assistance of two hands. Last Saturday night the three young gentlemen, who had spent the evening on shore, walked together down to the beach about 11.30, and entered the punt which was anchored there, and proceeded to the *Vixen*, which was moored about a quarter of a mile away. When about half the distance to the yacht had been traversed, one of the young men turned round suddenly, and leaned over the side of the punt, and in an instant the water poured into the frail craft, which capsized, throwing its occupants into the water. Not one of the three appears to have lost his presence of mind, nor, in fact, to have been much alarmed at the accident, and one of the two who were drowned, in fact, called out, "Are you all right, Browne?" Browne replied, "I am all right; look out for yourselves." Whereupon Lange and Frame struck out for the shore, and Brown heard no more of them except some splashing. Seeing that, as he thought, his friends were all right, Browne turned his attention to his own safety, and got hold of the capsized punt, which was floating, keel upwards, close by. Several times he managed to get on the keel, but as often as he did so the punt slipped from under him, so finally he got hold of it, and, pushing it before him, at last managed to reach the shore safe and sound. Then he looked out for his friends, who he supposed had reached the shore before him, but he could see nothing of them. He shouted "Frame" and "Lange" several times, but got no answer. The bodies of the two young men were subsequently recovered. One of Lange's boots and his cap were missing. These were later washed ashore, when it was found that the boot was half unlaced, indicating that a desperate attempt had been made by the poor fellow to lighten himself by getting rid of his boots, in which, however, he was only partially successful.

## Patent News.

THE following applications for Patents were made between August 28 and September 2, 1899:—

**PHOTOGRAPHS ON SILK.**—No. 17,375. "Improvements in and relating to the Production of Photographs on Silk." F. J. FARRELL and E. BENTZ.

**KINEMATOGRAPHS.**—No. 17,405. "Improvements in Kinematographs." L. E. GRANTHASTEDTEN.

**DARK SLIDES.**—No. 17,415. "Improvements in the Construction of Photographic Dark Backs and the like." Complete specification. C. P. GORRE.

**FILMS.**—No. 17,446. "Improvements in Photographic Films." J. E. THORNTON and C. F. S. ROTHWELL.

**PROJECTION APPARATUS.**—No. 17,514. "Improvements in and connected with Optical Projection Apparatus." J. SZCZEPANIK.

**SWING BACKS.**—No. 17,521. "Improvements in Swing Back for Photographic Cameras." Complete specification. W. F. CARLTON and H. W. LOCKE.

**GAS FOR PHOTOGRAPHY.**—No. 17,522. "Improvements in Apparatus for Photography by Means of Gas." Complete specification. A. G. ADAMSON.

**PORTABLE DARK ROOM.**—No. 17,589. "A Portable Photographic Operating Chamber." Complete specification. F. SCHAETZKE.

**FILM-HOLDERS, &c.**—No. 17,737. "Improvements in Photographic Film-rolls and Roll-holders." J. E. THORNTON.

**SENSITISED PAPER CARDS.**—No. 17,738. "Improvements in Sensitised Papers, Cards, and Other Materials used for the Production of Photographic Prints from Negatives." J. E. THORNTON and C. F. S. ROTHWELL.

**SENSITISED PAPERS.**—No. 17,739. "Improvements in Photographic Sensitised Papers and the like." J. E. THORNTON and C. F. S. ROTHWELL.

**MOUNTS.** No. 17,741. "Improvements in Photographic Pictures and in the Materials or Mounts Therefor." J. E. THORNTON and C. F. S. ROTHWELL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

September.	Name of Society.	Subject.
18.....	South London .....	Demonstration: Photographic Printing by Carbon Process. Mr. Skelton.
19.....	Gospel Oak .....	Exhibition and Criticism of Members' Lantern Slides
19.....	Hackney .....	Concerning Exhibitions and Competitions. W. D. Welford.
20.....	Photographic Club .....	Discussion: Uncorrected Lens Work.
20.....	West Surrey .....	Open Night.
21.....	London and Provincial .....	The Kromax System of Colour Photography. T. Knight Barnard.
23.....	South London .....	Excursion: Ewell. Leader, H. Esler.

**Hackney Photographic Society.**—September 5, the President (Mr. W. F. Fenton-Jones) in the chair.—The EXCURSION SECRETARY announced that in the July excursion competition the marks had been divided by Messrs. Hunt and Selfe. The Hon. Secretary demonstrated the working of Vicol paper. It is a print-out paper, which has to be treated the same as other kinds of P.O.P. up to the making of the finished print. The feature of the process is that colours may be produced in the prints by the local application of different solutions. The solutions are: A. Citric acid; B. caustic soda; C. pyro. The application of these produce respectively pink, blue, and yellow, while a mixture produces other shades. The demonstration was quite successful. The President then showed the biokam, a small instrument for taking "living pictures." It is very ingeniously constructed, and combines in itself an instrument for taking, printing, and projecting the pictures. Among other features it has two Voigtlander lenses, and is sold complete at six guineas. About half a dozen subjects were shown on the screen to illustrate the capabilities of the instrument.

**North Middlesex Photographic Society.**—September 11, Mr. S. H. Fry in the chair.—Mr. J. W. MARCHANT read Mr. H. T. Malby's Affiliation lecture on

#### THE PHOTOGRAPHY OF FLOWERS.

The lecture was very practical, and was illustrated by some good slides. On its conclusion, one of the members said that no guide was given by the lecturer as to the exposure required, and asked for information on that point, whereupon several members gave their experiences in this direction, and, as they differed very considerably, it is to be hoped he was not more mystified than before. Mr. H. W. BENNETT made a few remarks upon the paper. Talking of colour screens for this work, he said he had found that some flowers, although to the eye they seemed the same colour as another kind, required a screen to get the proper effect, while the latter did not. A very useful tip for this work was to use, instead of a tripod, a piece of wood wide enough and strong enough to bear the weight of the camera, about four or five feet long. The camera was fastened upon one end, while the other was screwed down by a single screw to the table upon which the flowers were placed. The advantage of this arrangement lay in the fact that you could get the best position from which to take them by simply swinging the board from side to side as required. The board should be grooved, so as to enable the camera to be moved to and fro. Another point was that better colour rendering was obtained by a long exposure than by a short one.

**Rotherham Photographic Society.**—The autumn and winter session was commenced on Tuesday night, September 5, when there was a good attendance to witness the Hon. Secretary (Mr. Hemmingway) give a demonstration of the working of the platinotype process, cold bath. The chemical and historical side of the subject received some attention. The Platinotype Company kindly sent a number of beautiful specimens. Special prizes, offered by Messrs. Marion & Co. and Paget Prize Plate Company, for photographs taken in connexion with the Decorated Horse and Carriage Parade on Bank Holiday, have all been secured by members.

### FORTHCOMING EXHIBITIONS.

1899.	
Sept. 22–Nov. 4 .....	Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
„ 25–Nov. 11.....	Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.
October 18–24 .....	Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.

- October 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
 Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.  
 December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.  
 „ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE R.P.S. EXHIBITION.

To the EDITORS.

GENTLEMEN,—Enclosed is copy of a letter I am just sending to the General Committee of the Royal Photographic Society, and I shall be glad if you consider it of sufficient interest to insert in your JOURNAL.—I am, yours, &c.,  
 LYDELL SAWYER.  
 230, Regent-street, W., September 10, 1899.

[COPY.]

“September 9, 1899.

“To the General Committee, Royal Photographic Society.

“GENTLEMEN,—I sent by hand a contribution of pictures to your forthcoming Exhibition at the earliest moment on the morning of September 7, after being prevented by an accident from delivering by nine o'clock on the night of the 6th, as I endeavoured to do. I was excessively surprised to find it rejected by both the Secretary, and later by the Selecting Committee, owing to late arrival! I respect legitimate rules, but I must state that this regulation is one of aggressive, tyrannical injustice, and paltry and spiteful as to its slight necessity, and immoral as to the extensive injury of its effects.

“It is a matter which might be fairly met by a little limited discretionary power being relegated to the acting Secretary, but it suggests, rather, a reactionary revenge for some former trouble through previous excessive laxity of your own laws. I may be expressing myself strongly, but I have also strongly before me the Peckaniffian smugness of a petty regulation which says to the would-be exhibitor, ‘You may have worked hard; you may be right in stating that your very anxiety to produce creditable work has delayed you, or an accident has checked your progress, but that is your affair. We quite ignore your imputation that we are called upon either to encourage exhibitors or to consider the quality of the work we may reject from our Exhibition. We are not concerned with the fact that some exhibitions are able to open within a few days from receiving their complete contributions; it suffices that we prefer seventeen full days. We are only concerned so far as we find by our official watch, Sir, that you are four minutes late, therefore do we have much just satisfaction in making you an example for attempting to trench on our Medes and Persian-like laws.’

“Personally, such an action, at the present moment, is of little importance to me, but, in earlier times, I have worked earnestly for months for the purpose of contributing to your Exhibition, and then such scant courtesy would have been a seriously cruel blow.

“I learned, on the early morning of September 7, also, that other exhibits as well as mine had already then been thrown out. The Secretary had no alternative; but are you, as a ‘parent’ Society, content that you are doing your duty in thus probably quenching the enthusiasm of anxious aspirants for so little fault or cause?—Yours faithfully,  
 (Signed) LYDELL SAWYER.”

[Other letters complaining that photographs intended for exhibition were denied acceptance by reason of late delivery have also reached us. We are sure that Major-General Waterhouse and the other responsible officers of the Society sincerely regret having to refuse photographs which are not delivered by the time specified in the regulations (which have been in circulation for nearly two months), but we believe we are correct in saying that those regulations do not invest the officers with any discretionary power in the matter of receiving late exhibits. Some such power as this might be delegated to them in future, but it is safe to say that, whatever concessions are made in the matter, there would still be late comers. We are sorry Mr. Sawyer's exhibits were excluded; but, from our knowledge of the internal management of the Society, we are in a position to assure him that the motives he ascribes for their rejection are entirely non-existent.—EDS.]

### THE STEINHEIL LENSES.

To the EDITORS.

GENTLEMEN,—The abstract of Dr. Rudolph Steinheil's article in Eder's *Jahrbuch* for 1897, which Mr. P. E. B. Jourdain has communicated to you, contains information of considerable importance to photographic opticians; but, as there are several mistakes of detail which may render it unintelligible to many of your readers, I take the liberty to offer the following corrections. An important fact connected with the improvements which Messrs. C. A. Steinheil Söhne have effected in their photographic lenses is the return to the symmetrical form of construction. The various stages of evolution are indicated by the periscope, the aplanat, the antiplanat (not antiplanat), and the orthostigmat. The older kinds of glass imposed limitations which drove Adolf Steinheil to the antiplanatic construction, but, as soon as the new glasses were discovered, he returned to the aplanatic type, and set his son, Dr. Rudolph Steinheil, the problem of calculating the orthostigmat. In Mr. Jourdain's communication this is unfortunately described as an “antiplanat” (THE BRITISH JOURNAL OF PHOTOGRAPHY, page 551, line 6), whereas it is in reality an aplanat anastigmatically corrected. With reference to the refusal of the German patent for orthostigmat, Type I., the remark in paragraph 5, page 551, should read, “The next thing to be done under these unfortunate circumstances was to come to an understanding with the more lucky applicant, Goerz.” It was never contemplated to “unite” the firms of Goerz and Steinheil, only to secure a licence for the manufacture of the lens, Type I., upon equitable terms. With regard to the latter part of paragraph 7, page 551, I may add that Messrs. Steinheil have withdrawn their application for the German patent for orthostigmat, Type I., as Type II., for which the patent has been granted, is a better lens. The aperture of this is f.6.8, not f.6.8, as stated in paragraph 8, page 551.

Concerning the wide-angle aplanat, Mr. Jourdain's communication states in paragraph 2, page 550, that the astigmatism was corrected “at the expense of sharpness and flatness of object.” This should read: “At the expense of intensity and flatness of image.” In the same paragraph the remark concerning the periscope should read: “The first result of his labours in this direction was the periscope, a double objective consisting of one sort of glass only. For this reason it was marred by the non-coincidence of the visual and the chemical foci, but in all other respects it fulfilled the conditions of a photographic objective.” Concerning the group-antiplanat, the statement that “it could not be made to act satisfactorily on account of the sorts of glass which were then obtainable” is rather misleading. The old kinds of glass did not permit of more satisfactory results being attained with this type of construction, but in some respects it was an improvement upon the aplanat, and, until the discovery of the new glasses, it enjoyed a considerable reputation, and is, in fact, still recommended by Messrs. Steinheil for use with their tele-photo attachment.

It may also interest your readers to know that Messrs. Steinheil, whilst calculating the orthostigmat, also improved the antiplanat, by introducing another element in the back combination. This lens is known as the rapid antiplanat, and ranks next to the orthostigmat. They have also improved their wide-angle copying lenses of the aplanat type by adding another element to each half. These facts are worth noting as stages in the evolution of the anastigmat or orthostigmat.—I am, yours, &c.,  
 P. EVERITT.

September 6, 1899.

### CLOUDS.

To the EDITORS.

GENTLEMEN,—I think it will be generally admitted that, to give the true and natural effect of clouds in a landscape, the clouds should be those that appear in the sky at the moment the photograph is taken. To introduce clouds into a landscape taken on a cloudless day, or to print in clouds other than those that are present when the photograph is taken, cannot be a truthful representation of the subject. The aspect of a landscape changes as the clouds change, and as the direction of the light changes with our relative position to the sun at different hours of the day. For example, a landscape taken at noon and the clouds taken on the morning of the same day—or at any time of the day except the time at which the landscape is taken—will produce the most incongruous effect, to say nothing of the effect which is produced by the indiscriminate introduction of clouds taken at all periods of the year, and at all hours of the day, without the least regard to chiaroscuro, direction of the light, or character of the subject. Why this objectionable method should be so largely resorted to I do not understand, as there is really no difficulty in taking cloud and landscape together in one exposure. In most of the landscapes I have taken—in all of recent years—clouds have been secured with one exposure. Where there are no clouds, I never attempt to print them in, I soften the effect by sunning down the sky, which, as Mr. W. J. Croall truly observes, “adds not only to the pictorial quality of the picture, but lends value, if not grandeur, to the subject.” I have an arrangement which I have used for some years past for taking clouds and landscape with one exposure, a sketch and description of which I hope to send you shortly, also a print showing a solitary white cloud in the sky—not taken on a rapid plate with an instantaneous shutter, but on a comparatively slow plate with an ordinary plate shutter to which the arrangement referred to is attached.—I am, yours, &c.,  
 COLONEL.

## STUDIO BUILDING: TO "CLARINETTE."

To the Editors.

GENTLEMEN,—If I had had the private address of above querist, I should have sent him my experiences in studio building.

I paid a sum of money for a house (24) which was then (jokingly) considered to be mine, and, being desirous of a photographic studio at bottom of garden, arranged with Messrs. Humphries, of Knightsbridge, to erect one of iron and glass for about 20*l*. This was done, and I commenced comfortably spoiling plates, when an individual walked in, said he was the district surveyor, and, while expressing extreme sorrow, intimated that erection must be taken down, and three feet from ground built with brick. You may be sure this was not done without protest, but it was eventually done, and again I began to enjoy myself, when, one day, two four-wheel cabs brought down eight or nine gentlemen, calling themselves a visiting committee from the ground landlords, the Haberdashers' Company. It seems that a gentleman living next door had lodged a formal protest against my studio, said it hindered his view (a coal yard). The roof was consequently lowered one foot, so that altogether the building, instead of costing 20*l*., ran me, or some one else, into the expense of 60*l*.

I should have been pleased if "Clarionette" had thought it worth his while to have called and seen what it came to at last.—I am, yours, &c.

WILLIAM JAMES BEARNE.

24, Drakefield-road, Nunhead, S.E., September 6, 1899.

## HOT-WEATHER PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—In the interesting letter, entitled "Hot-weather Photography," in your issue of the 8th inst., I hardly think your correspondent lays sufficient stress on the exceptional conditions under which this enthusiastic amateur worked.

A rainfall of five inches per hour is almost if not quite unknown in England. During the year 1898 the heaviest fall of rain was 6·7 inches in three hours, and the damage done by this storm here alone to roads, bridges, &c., cost over £750. The average yearly rainfall in England is roughly about thirty inches, and one-tenth of an inch per hour is considered a very good average fall.—I am, yours, &c., A. VICTOR HASLAM.

Breadsall Priory, Derby, September 9, 1899.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

A. WEST; T. KING; W. G. ORME; T. S. M. W.—We are obliged to hold over replies to these and other correspondents until our next.

COLOUR.—You should succeed by the aid of Messrs. Cadett & Neall's spectrum plates and one of their light filters.

GEORGE HOLLAND (Mid-Cheshire Society of Art).—Better address our weekly contemporaries. We do not send out sets of lantern slides for the purpose named.

W. H. HUNT (Willesden Green).—Thanks for your letter and the enclosures, which we will keep by us. If the opportunity comes to us of bringing the matter to the notice of likely persons, we will avail ourselves of it.

POSITION OF BRIDE IN A PHOTOGRAPH.—WEDDING asks: "Please let me know which is the correct position for a bride to occupy in a wedding group. Should she be to the left or right of bridegroom?"—We are not sure that there is any set rule, but we think on the left.

ACETO-CELLULOSE.—ACETO says: "Having read the article on aceto-cellulose in THE BRITISH JOURNAL OF PHOTOGRAPHY, I wish to know if you can inform me where I can obtain it, or would you print formula of the same in your Correspondence column?"—So far as we are aware, aceto-cellulose is not an article of commerce. Better communicate with Messrs. Cross & Bevan, New Inn, W.C.

VARIOUS QUERIES.—P. H. ADAMS says: "I shall be glad if you will answer the following questions, giving the address of secretaries: 1. Is there a trade union for photographic or process operators? 2. Please give address of Secretary of the Photographic Copyright Union. 3. Which is the best all-round handbook on process work? You refer one of your readers to the ALMANAC, p. 639, which I have not got, for particulars of Copyright Union last week."—In reply: 1. No. 2. H. Gower, London Chamber of Commerce, Botoolph House, Eastcheap, E.C. 3. *The Half-tone Process*, by Julius Verfaesser, published by Percy Lund & Co., Bradford.

FORMULÆ WANTED.—INK says: "Will you please give two or three good formulae for sensitive collodion for wet plates?"—We scarcely understand this query. Collodion for wet plates is not sensitive. It is simply iodised, and is made sensitive by immersion in the silver bath. Formulae for both are given on pp. 1055-6 of the ALMANAC. Possibly, however, a collodion emulsion is meant. If so, formulae for that are also given on pp. 1057-8. These plates are usually used dry, but they may be exposed wet.

AVOIDANCE OF GRAIN IN COPYING.—G. BARKER says: "I should be obliged if you can tell me how to get rid of or avoid the grain of paper in copied photographs. I have copied several lately, and got good negatives, only the grain of the paper is too obtrusive."—In reply: The grain may be avoided by the proper lighting of the photograph to be copied. Employ well-diffused light, and, if possible, take the photograph vertically. Have the print as far as possible from the source of light, so that the surface irregularities do not cast shadows. It is all a question of lighting.

BOOKS WANTED.—A. P. S. says: "Can you tell me what are the best books for studying the following subjects, their prices, and publishers: (1) Photographic emulsions; (2) coating of photographic papers; (3) machinery used in coating and preparation of emulsions?"—In reply: (1) *Abney's Photography with Emulsions*, published by Sampson Low & Co., St. Dunstan's House, Fetter-lane, E.C.; (2 and 3) *Just's Bromide Papers*, published by Percy Lund & Co., Bradford, and Woodbury's *Gelatino-Chloride Printing*, published by Hazell, Watson, & Viney, 1, Creed-lane, E.C.; but there is not much practical information available in regard to 2 and 3.

STAINED PHOTOGRAPHS.—G. B. H. says: "Enclosed are two photographs which have been stained in some part of the process. A good deal of argument and a number of opinions have been given as to what cause and at what stage of the process it occurred. Eventually it has been decided to submit the decision to you. Will you, then, be kind enough, in your next issue of the JOURNAL, to give your opinion as to cause?"—It is quite impossible from simply looking at a couple of prints to say the immediate cause of the staining. All one can say is that it is due to faulty work, but not at which stage of it the stains are due. The prints rather look as if the water in which the free silver was washed out was contaminated with hypo.

SIMULTANEOUS DEVELOPMENT AND EXPOSURE OF BROMIDE ENLARGEMENTS.—GIT says: "To obviate the difficulty of determining the exact exposure for bromide enlargements, a correspondent of the *Wochenblatt* recommends that, before exposure, the surface of the sensitive paper be treated with a developer incorporated with glycerine. The growth of the image after or during exposure can be watched and arrested at proper depth. Subsequent development can be resorted to for modifying the character of the image. 1. How much glycerine should be added? 2. Will iron developer suit? 3. How long should the surface be treated? Any other hints will greatly oblige."—We know nothing more of the method than was published, and we have not tried it. Possibly some reader who has experimented with it will give his experience for the benefit of our correspondent.

INTENSIFICATION; AN EXCHANGE TRANSACTION.—VEXED says: "1. I have with bichloride of mercury intensified a valuable negative, and to reduce a part of it I wiped it with hypo, then washed. The parts wiped have now got a thick dull stain, which acid or hypo does not remove. 2. About four weeks ago in the JOURNAL I advertised an autocopyist for exchange. After mutual agreement by post, I accepted a half-plate camera and tripod. I valued autocopyist at 4*l*.; he valued his kit at 3*l*. 10*s*. to 4*l*. We both sent our things. I am dissatisfied, for his kit is very ancient and knocked about, and not worth 10*s*. I ask him to send me 1*l*. to satisfy me, or half of what he values it at, viz. 1*l*. 15*s*., and I will return the lot. His last letters are disagreeable, and he describes mine as all bounce. How can I get redress, or the return of autocopyist?"—1. Evidently the negative was not sufficiently washed after each operation. The only thing we can suggest is to bleach the negative again in the bichloride solution after well washing, and intensify afresh. 2. The only way is through the County Court, but you will have to prove misrepresentation. It was unwise to make the exchange before seeing the articles.

COLOUR PHOTOGRAPHY.—D. E. says: "I am preparing a paper for an address on the 'Reproduction of Colour by Photography.' Can you tell me where I can obtain particulars of the experiments of Seebeck, Herschel, Becquerel, Abney, and any others who may have experimented in photography in natural colours? I believe they all produced photographs in tints more or less true to nature, but could not fix them. Is this so? I am a member of a photographic society affiliated to the Royal, and therefore presume I could consult any books in the library of the Royal, and should be prepared to spend a couple of days in London to look up the particulars. I should like to show prints reproducing the results obtained by the early experimenters. There is a semi-prophetic paper by J. W. Swan in the *Year Book* for 1870. He says these early results were achieved by using a sensitising compound that went through various changes of colour dependent on the exposure, and that we should never get photography in natural colours till we got a substance that would turn green, say, because green light shone on it and independently of the exposure. This sounds right."—In reply: An article on the subject of colour photography, in our ALMANAC for 1889, will supply you with the groundwork of the subject. Undoubtedly, a reference should be made to the books in the Royal Photographic Society library, which contains most, if not all, the literature on the subject. You are correct in the main as to the inability of the experimenters named to fix their results. We doubt if any such specimens are available for the purpose. Thanks for the reference to Mr. Thorpe.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The

formulae will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

A MOST interesting “link with the past” was present at the Missouri State Convention of photographers last month. This was Mr. August Brassant, who informed his hearers that he was eighty years old on July 6 last. He was born in Paris, and was employed there as an apprentice in the shop of the man who was silversmith to the King of France. Mr. Daguerre came to his shop one day to ask if they could furnish him with smooth plates that were made simply by polishing by hand. “My employer told him no, it could not be done. He turned to me and said, ‘Well, young man, can you make a plate perfectly finished by hand? Can you do it?’ My employer stood behind him and motioned to me to say no. I was struck with a great astonishment. I reflected a moment, and said, ‘Yes, I can do it.’ Mr. Daguerre was so surprised that he patted me on the shoulder, and said, ‘Well, young man, go to work.’ I worked for two or three weeks without knowing what it was for. At that time the dry plate was unknown—in 1838

—and on that account it required two hours' exposure to take a picture. After that time I worked for some time on the plates; then I became a photographer, which business I followed until about four or five years ago."

\* \* \*

A FEW weeks ago we announced the formation, in the United States, of the General Aristo Company, which, with a capital of 5,000,000 dollars, combined the whole of the important sensitive printing-paper manufactories under one head. Remarks on the probable effects which this unprecedented combine might have on photographers and others have led to the publication of the following official explanation, which, it is hoped, may reassure the American public: "The General Aristo Company," we are told, "is not a trust in any sense of the word. It is a Company formed which purchases outright the paper business of the Eastman Kodak Company, the American Aristotype Company, the Nepera Chemical Company, the New Jersey Aristotype Company, the Photo Materials Company, and the Kirklands Lithium Company. It is an absolute consolidation under one company and one capitalisation. It is not a combination of interests of several individual concerns handled by promoters who do not understand the business and have no interest at stake except the profit of stock manipulation, but a Company which pays down good money for these various companies, and have as much at stake in the proper care of their consumers and in the reputation of their goods as any one of the individual concerns had previous to the consolidation. . . . There will be no increase of price, and the Company will not permit any competition to undersell them, quality considered. The General Aristo Company will control for North America the raw-paper products of the Rives and Steinbach mills of France and Germany. Aside from this, their power of purchasing other materials will be greatly enhanced, which will enable them to give better goods and better service for the money than any other photographic concern in either hemisphere."

\* \* \*

*Apropos* of trusts and combinations, we gave publicity a few months ago to some details of an attempt now being made in the States by a Mr. Kurtz, acting in conjunction with a Colourtype Company, to "set up a claim to all patent rights in three-colour block-making, and thus get the whip hand of those practising the process. Of course, Kurtz's patents were antedated many years ago, but the fact appears to have been overlooked by those most concerned, probably through ignorance. However, Mr. Weeks, of Philadelphia, published a letter, about a month ago, which should effectually put a stop to any further attempts at "frightening the photographic public in the States. Mr. Weeks says: "In 1881, twelve years before Kurtz's patent, my friend Mr. Ives, of Philadelphia, who was at that time the only practical half-tone worker in the United States, made three-colour plates, using single-line screens, with parallel lines running in one direction only, and the lines in one plate running in a different direction from the lines in the other plates. At the present time Mr. Ives has, framed in his office in Philadelphia, proofs which were made in this manner in the year stated, that is, 1881. These same proofs were exhibited by him in the Newtelties Exposition in 1884, [nine years] previous to the date of the Kurtz patent. Mr. Ringler, of the Colourtype Company, recently visited Mr. Ives, and had this [matter entirely

explained to him, and also had the prints referred to, which bear the date of their execution, shown him. In view of these facts I see no cause for any worryment on the part of any one wishing to operate the three-colour process, whether by single or double-line screens, as Mr. Ives can effectually dispose of the Kurtz patent. We are not working the three-colour process at the present time, although, having made all arrangements to do so, we will very soon have that department in operation, and hereby extend a cordial invitation to Mr. Ringler or Mr. Kurtz to visit our establishment. For the benefit of the craft I would be glad to have you give this matter publicity, and would say that we can produce plenty of good witnesses who can testify as to the time that Mr. Ives did the work specified, and it will afford us considerable pleasure to do so." This peculiar form of patent-farming which Mr. Weeks so clearly discounts, is not known here, it is true, but, as our readers are aware, the reinvention and exploitation of old colour processes is no uncommon thing among us.

\* \* \*

MR. RICHARD KEARTON recently visited Scotland in order to complete the information for his new book. He entitles it *Our Rarer British Breeding Birds*, and that describes its subject. Mr. Kearton and his brother, Mr. C. Kearton, co-operate on a book, the latter being the picture-getter. He has planted his camera in almost inaccessible places.

\* \* \*

At the recent American Convention the Nepera Chemical Company, the introducers of Velox, exhibited a machine by means of which a large number of Velox prints can be made in a few hours. The machine consists of a small box about two feet long by a foot wide and a foot deep, and contains a roll of sensitised paper from 200 to 300 feet long. The negative is placed in the lid of the box and the sensitised paper passes along beneath it. Once a correct exposure is obtained only two motions are necessary for each picture. A lever is drawn up, which exposes the paper beneath the negative and also registers itself on a small cyclometer; another handle is turned, which causes to pass beneath the negative the strip of sensitised paper. With these two simple movements it is possible for the operator to turn out 5000 or 6000 prints in a single day. As the exposure is in every case exactly the same, it is natural that one print is exactly like the other. The Company exhibited the machine at work, and it attracted a great deal of attention. For printing on Velox paper the machine should be in great request.

\* \* \*

COMMENTING on some simple directions recently given in the *English Mechanic* for viewing binocular prints without the aid of a stereoscope, a correspondent of that journal says that squinting inwardly does not produce the true stereoscopic effect, because the vision crosses, so that we see with the left eye the picture that we ought to see with the right, and *vice versa*, the result being a sort of reversal of the perspective—curious with geometrical figures, but false and quite unnatural with ordinary views. To get the true stereoscopic effect it is necessary to squint *outwards*, just enough to bring the two pictures into one. "This is by no means such an easy feat as the other, and I cannot do it myself, but I have seen it done by an accomplished photographer, who habitually tests his stereoscopic work in this way. To make sure that you are squinting outwards it is necessary, at the outset, to place a

partition between the eyes, reaching from the nose nearly to the line between the two pictures. Possibly many have the power of squinting outwards at will, but it does not strike me as a very wholesome exercise to squint either way—for young people at all events."

\* \* \*

THE writer of this letter is in error on several points. For viewing binocular pictures without a stereoscope it is not necessary to squint inwardly, *i.e.*, cross the axes, or outwardly, that is, to diverge them; it is not required to interpose a septum between the two pictures, and there is no question of "squinting" at all in the matter. As we understand the way in which the eyes may be accommodated to acquire facility in seeing binocular pictures stereoscopically, neither convergence nor divergence of the optic axes is required. On the contrary, we take it that the optic axes must be virtually parallel at the normal distance of distinct vision, that is, from eight to ten inches. Ordinarily, in viewing objects at that distance, the axes are converged, and, when for a real object we substitute a stereoscopic photograph, it is obvious that it is not axial convergence which is required, but some such control over the ciliary muscles as will enable the left eye to see the left-hand picture, and the right eye the right-hand picture. If this simple principle were generally grasped, the nonsense that is written about injuring the eyes by this method of obtaining muscular control over them would be considerably diminished.

\* \* \*

THE newspapers last week contained accounts of two methods of increasing the power of acetylene for illuminating purposes. One process is that of an engineer of St. Petersburg named Celowsky. He impregnates the calcium carbide while hot with a mixture of 1 part (by weight) of tar and 40 parts of petroleum residue. The hot carbide coming from the furnace absorbs the mixture throughout its bulk. The "Elyte" thus made is not affected by air, and in water it disengages acetylene very slowly and regularly. When it is taken out of the water and no longer drips, it ceases to yield the gas. The production of acetylene is increased by it some ten or twelve per cent., and it is otherwise more convenient than simple carbide. The other new illuminant was demonstrated at Hunmanby, a village just outside Filey, last week, at the initiative of the Scarborough District Lighting Company, Limited. Hunmanby is the first place in England lighted with the new illuminant. It has been installed in the church, and at Hunmanby Hall (the residence of Lord William Cecil), and in a number of shops. Mr. T. G. Marsh, who introduced the penny-in-the-slot system, is arranging for a supply of the new gas to smaller consumers on the prepayment principle. It is said that Electroid gas is composed of acetylene, oxygen, and a "third substance." It gives a light of great purity and brilliancy. The Scarborough District Company intend lighting many villages and mansions throughout Yorkshire with it.

\* \* \*

WE are asked to announce that the Annual General Meeting of the members of the Photographic Copyright Union will be held on Tuesday evening, September 26, at the Café Royal, Regent-street, W., at eight p.m. Those intending to be present should note the fact that a change in the meeting-place has been made this year, from the St. James's Restaurant to the Café Royal.

THE London County Council, in their annual report, ask for further authority in the matter of cinematograph entertainments, which are now frequently given in places over which they have no control, and which, by reason of the danger attending them, it is claimed should be under rigid inspection. It is obvious that school buildings, places of worship, and similar edifices, are aimed at in this request, which, it appears to us, is a perfectly reasonable one on the part of the Council.

#### SEPARATION OF THE LENSES IN STEREOSCOPIC WORK.

A CORRESPONDENT asks us to devote an article to the subject of the adjustment of lenses in stereoscopic work. The reason he gives for his request may be thus stated. In ordering a stereoscopic camera to be made with the lenses so attached to the front that their distance of separation could be varied, he was met by the following pronouncement from the firm of camera-makers with whom he was in communication: "We note what you say with regard to the adjustment of lenses for different distances, but we are still of opinion that it is more of a theory than of practical value, and this view of the case is also shared by Messrs. —, to whom we have referred the matter."

We are aware that many firms who, in America and this country, as well as on the Continent, make hand and stand stereoscopic cameras for general use, do not trouble to give an adjustable movement to the lenses, for the obvious reason, of course, that amongst stereoscopic photographers there is very little call for the useful power which this convenience would place in their hands. Nevertheless, amongst the comparatively few persons who have a thorough grasp of the underlying principles of stereography and the important bearing they have as regards correctness of application to practical ends, the utility of adjustable objectives in binocular work is so great that we may profitably take occasion to point out a few of the many reasons why that power is practically as well as theoretically of value.

In binocular vision our appreciation of relief, height, and distance is governed entirely by the power of axial convergence which our eyes possess. If we look at an object which is situated, let us say, at a distance of half a mile, the optic axes are virtually parallel; at any rate, the parallactic angle is so small that no sensation of relief results. In other words, as regards an object situated at the distance named, the two eyes, instead of seeing dissimilar views of it, as in the case of objects situated only a few feet or yards from the observer, virtually perceive them as identical. There is no "seeing round" either the one side or the other of the two similar views which are transmitted to the retina.

What applies to the eyes in the case of this narrowness of parallactic angle applies also to the lenses on the camera front. No relief is seen in distant parts of the binocular photograph; but the comparison does not hold good when we come to objects situated within a few feet or yards of the camera. The eyes, by their powers of accommodation and axial convergence, see those objects in natural relief; but, inasmuch as the lenses situated at a distance, we will suppose, of three inches from centre to centre on the camera front, possess neither the power of accommodation nor that of axial convergence, they impart to those objects, when they are viewed in the prints, an aspect of excessive or rather exaggerated relief. They see too much round the subject. Let the portrait of a person be taken with

three-inch separated lenses, four or five feet from the camera, and the effect described will be at once apparent in the stereo-photograph.

It can be seen, therefore, that the need of adjustability in lenses for binocular work is a real, and not an imaginary, one. Suppose one is photographing a vase of flowers, situated a few feet from the camera. In practice, a separation of two inches is sufficient to give natural as opposed to strained relief, which would make the object have a cut-out or model-like appearance. In portraiture a separation of two and a half inches suffices. For interiors and landscape work, three inches should separate the centres, and where, as in the latter class of photography, the nearest prominent object may be hundreds of feet or yards away, a separation of three and a half or even four inches may be adopted.

It all comes to this: the nearer the object to the camera, the less the separation; the more remote the object, the greater the separation. We have known of stereoscopic photographs of objects placed immediately in front of the camera being taken with a separation of only one and a half inches between the lenses. On the other hand, instances may be recalled where, when stereo-photographing distant objects, yards have separated the objectives, and there is the well-known case of the binocular photograph of the moon, taken, so to speak, with the lenses separated many thousands of miles. Here we have the two extremes of the principle brought into force.

It is in the photography of objects placed near to the camera that the value of being able to adjust the centres of the lenses chiefly asserts itself. Half an inch in the separation makes all the difference between naturalness or exaggeration of relief. It is the latter defect which offends so many of those who examine stereo-photographs for the first time. In nature, no matter how near an object may be to the eye, we are not conscious of its possessing exaggerated relief. The baseline of the parallax angle formed by the eyes is approximately two and a half inches. When, however, a stereograph of the same object, taken under conditions which lengthen the baseline to three or even three and a half inches, is presented to the eyes it is not difficult to conceive that the mental impression so produced differs vastly from that which is the result of an examination of the original by ordinary vision. In the latter case we have the sense of reality; in the former, the impression of unreality.

We might extend this theme indefinitely. Sufficient, however, has probably been said to show that, when it is desired to take the fullest advantages of the power of making stereographs of objects situated very near the camera as well as those lying in more distant planes, adjustable objectives become something more than a convenience—viz., a necessity.

**Solid Hydrogen.**—One of the interesting features of the Chemical Section at the meeting of the British Association was an account, by Professor Dewar, of his success in the solidification of hydrogen. He explained that, when solidified, it presented the appearance of a clear, colourless solid, resembling ice, and sometimes like frosty snow, and not at all like mercury, as had been anticipated. In the course of the discussion which followed it was announced that Professor Dewar had also succeeded in liquefying helium, one of the newly discovered atmospheric gases. Now the liquefaction and solidification of all the gases is brought about under enormous pressure and an intense degree of cold, and it is surprising that no

serious accidents during the experiments have happened through the bursting of the apparatus from the immense pressure within. It speaks well for the excellence of its construction as well as for its design.

**The Irrepressible Cinematograph.**—No event of interest, however little, seems to take place now without its being cinematographed. It does not matter whether it be a jubilee procession, the launch of a vessel, a photographic convention, a prize fight, a bull fight, or anything else, it is cinematographed. We read that, at the embarkation of the troops for South Africa at Southampton on Saturday last, as they crossed the gangways they were cinematographed. There is little doubt that, if war does unfortunately come about in South Africa, enterprising cinematographers and photographers will not be far off. It is related of one of the old "peep-shows" that were common at street corners some forty or fifty years ago that the showman used to tell the small boys, when showing the Battle of Waterloo, "There, at the back, is the Duke of Wellington and Buonaparte fighting a duel, but you can't see them because of the smoke." Smoke, now that smokeless powder is so much used, will not so much interfere with photography on the battlefield as it has done in previous wars when photography was attempted.

REFERRING to photography on the battlefield, it may be mentioned that the late Mr. Roger Fenton was the first photographer who essayed photography at a seat of war. In the Crimea, Mr. Fenton, with a 15 × 12, if not larger—we think it was 18 × 15—camera, secured some excellent pictures. Mr. Fenton worked, if we mistake not, both the wax-paper and the wet-collodion processes, and the results were published. It would be interesting to know where these negatives are now, as they possess great historical interest, particularly as showing what was accomplished in those early days under most adverse conditions.

**The British Association.**—The British Association's meeting at Dover has not been prolific in matters relating directly to photography, though it has figured indirectly in several ways. For many years past at these meetings little notice has been taken of the subject of photography as photography, although it has made many strides during the past few years, and many new facts discovered, which, though they may not have immediate practical value, are still important from a scientific point of view, yet they have not figured at all at these meetings. If we refer back to the meetings of twenty or thirty years ago, we shall see that the case was different then, for it was rare that one or more papers were not read on subjects directly connected with the art-science. In fact, the late Mr. Claudet seems to have contributed a paper to the Association almost annually. Why should photography, in its scientific aspects, be so much neglected by the British Association for the Advancement of Science now? Probably the answer is that there is no one at present sufficiently enthusiastic in the subject to bring it before the Association.

#### JOTTINGS.

THIS page of Jottings, by way of contrast to some of its immediate predecessors (which were Scotch), will have a decidedly American twang. Some weeks ago I remarked upon the fact that the British market was being supplied with enormous numbers of American-made cameras, and I gently chided our home manufacturers for allowing such things to be, forgetful for the moment, as my friend "Free Lance" has since reminded me, that there are several hand cameras of native construction which compete point by point with the American productions. To this matter I shall refer subsequently. Meanwhile I note that my remarks on the main subject have attracted the notice of a little journalistic eagle on the other side of the Atlantic, and that this brave bird is speaking out his wings and chortling in his joy (if I may be allowed to fit in here what sounds like a suitable phrase from "Jabberwocky") in a most triumphant fashion.

Thus: "Penrose & Co., in London, England, had to come to this country for a proper press to proof their half-tones. America got the contract for a big bridge in India, and had the thing up and off before the other bidders got out of bed. Velox is holding its head up proudly in England, France, and Germany; Kodaks ditto; Carbutt and Seed plates and films, Monroe cameras, and much else of American make is winning great favour abroad, which seems to rather wake up 'Cosmos' in THE BRITISH JOURNAL OF PHOTOGRAPHY this month. Here is some of what he says." And then my friend of the *Photo-American*, from whose pages I am quoting, goes on to mention what I said about the matter in these columns on July 28 last.

"No need," proceeds my critic, "to blush about having the good taste and common sense to prefer a camera like the Premo, for instance, instead of those beautifully made but clumsy old lumber yards the English makers turn out. I've seen lots of them and admired the exquisite handiwork; but, as for carrying one around, that's another thing; I beg to be excused. Three of their solid mahogany plate-holders, with slides as thick as packing-box stuff, make load enough, let alone carrying a camera, too. When it comes to English cameras, Americans are content to use their own make, and send Cousin John all he wants, too; for 'it is more blessed to give than receive' in this case."

To be just to this writer, he allows that English cameras are beautifully made. What finer photographic cabinet work could be desired than that which my late friend Meagher, Mr. George Hare, Messrs. Watson, Messrs. Rouch, and other firms have produced for many years past? I am here referring to stand cameras, of course, and I am open to back them for lightness and durability against any similar kind of instruments produced in America. Many readers of these lines, I am sure, have cameras by the makers named that have been in their possession for years and years, have made long journeys round the world, and have been used in the most trying extremes of climate, and yet are as good and as sound as when they left the maker's workshops. In this respect not even our highly ingenious American cousins could beat their British competitors, I am sure.

And, as to hand cameras, though the home-made articles are not so strongly in evidence as their American competitors, I fancy we are not so far behind in the matter of lightness and portability as the writer quoted seems to think. Really, not all English hand cameras are the "lumber yards," nor are the slides as thick as "packing-box" stuff, as he seems to be so anxious to believe. Messrs. Shew, Messrs. Beck, Messrs. Adams, Messrs. Rouch, Messrs. Redding & Gyles, and numerous other makers, have long been noted for very ingenious cut and rollable film cameras, which certainly cannot be called clumsy, and, above all, do not lack the crowning merit of durability. Were it not for hostile tariffs, it may be conjectured that a considerable number of them would find their way across the Atlantic, and then, perhaps, the Editor of the *Photo-American* would sing a different song. On the other hand, our friends over the water have to thank the blessings of free trade for the opportunity of "sending Cousin John all he wants," as the writer puts it.

"Cousin John," however, is denied the opportunity of returning the compliment. Strangely enough, a private letter from Rochester, N.Y., the seat of the American hand-camera industry, which I received a few days ago, contains the following paragraph: "Why does not some camera firm send cameras here? There is no cut-film camera on this market (United States), and I should think the Tella or Frena would go here." In a subsequent passage my friend gives the reason why he thinks cut-film cameras would be successful in the States. I have heard of more than one English manufacturing house which contemplates starting branches in the States. I am sure that our American friends would welcome competition on their own ground. At any rate, they could hardly complain of it.

From hand cameras to printing papers is a natural step. My correspondent, just quoted, gives me some details of the outbreak of opposition to the General Aristo Company, which was formed some time ago to combine all the large sensitive paper concerns in the States. He says: "Already several large jobbing firms are advertising a non-combine paper at fifteen per cent. less than the combine prices, and one large drug firm is importing paper and putting it into every drug store they supply with drugs." Evidently the General Aristo Company will have to fight hard to maintain its position. Combines or trusts of this kind do not thrive on English soil. I imagine that, if anything of the sort were started here, it would be equivalent to a signal for flooding the market with photographic manufactures from France, Germany, Belgium, and Austria, which are all practically next door to us and have free access to our markets. And our Continental competitors are not very far behind us in the science of catering for the requirements of photographers.

It is to be hoped that neither photographers nor photographic manufacturers who had intended being represented at the Paris Exposition next year will take any active part in the proposal to boycott the Exhibition which has been made by some emotional persons, not unnaturally shocked at the Rennes verdict in the Dreyfus case, and backed up by sensation-hunting journalists of the halfpenny London press. Leaving the political side of the matter out of the question, it is certain, from what has happened before in her history, that France will speedily forget and atone for the mistakes that have been made in her name during the past few years, and in that laudable desire she would be best supported by a hearty encouragement of her Exposition. Was it not the late George Augustus Sala who, soon after the Franco-Prussian War, wrote a delightful book descriptive of "Paris Herself Again?" Surely we all want to see France herself again; but the way to contribute to that desirable result is not by boycotting her Exposition and flinging mud at her because five military gentlemen's ideas of justice do not tally with our own.

It is from the two London photographic Exhibitions which open this week that a great many of the representative photographs for the Paris Exposition are to be chosen. I have had many inquiries from photographers as to how the process of selection is to be carried out. Few people seem to be aware that a joint Committee of the R. P. S. and the Camera Club has the matter in hand. Would it not be well if this Committee gave a little publicity to its existence? and may we know officially if, besides contributors to the Exhibitions, individual photographers who are not exhibiting will be given an opportunity of submitting work for selection? COSMOS.

#### AUTUMN AND AUTUMN WORK.

AUTUMN is now with us. The weather may not yet be "autumnal," but autumn is here all the same, and effects may be obtained at the present time that are not possible at any other period of the year. The foliage is yet full, though not perhaps so fully expanded as it was at the height of summer. The shadows are long, soft, harmonious, and transparent. In summer they are short and lacking in transparency, and look heavy in a photograph unless it is very full exposure is given and the development of the negative is very tentative. Those conditions do not obtain to the same extent at this season, by reason of the less altitude of the sun and its power; yet the light still is very actinic, often more so than when the sky is of a uniform blue and there are no light fleeting clouds about as there generally are now. We remember the late Mr. Vernon Heath stating, when giving evidence as an expert in a lawsuit, that the greater part of his best pictures were taken in the autumn. His famous series of pictures of Burnham Beeches, his best work in the opinion of many, were taken in the autumn; and by the shadows and foliage they show that such was the case.

While on the subject of autumn photography it may be mentioned that another effect may be obtained now that cannot be got, as a rule, at any other time unless under exceptional conditions. In the autumn and spring there are good and pronounced clouds about, and by judicious exposure and tentative development they can be secured in the negative

with the landscape, and no one will deny that clouds secured in the negative are infinitely better and more correct than any that can be printed in from a second one however good. But with negatives taken in the spring time the foliage is not at its full, as it is at the present time.

Again, at this season, about the time of the autumnal equinox, there are always a great variety of cloud effects obtainable that would be excellent for printing into pictures when clouds are not in the original negative, such, for example, as are taken in the summer, when there are no clouds in the sky. Therefore it is an advantageous opportunity for securing a stock of cloud negatives, for future use, while they are obtainable. While on the subject of cloud negatives, we would mention that the camera should not be, as is too frequently the case, pointed too much to the zenith. Negatives so taken will not harmonise with landscapes taken in the ordinary position of the camera; they should be taken with the camera placed as in taking a landscape. This may necessitate the camera being placed on an eminence, say a house-top, to secure an uninterrupted view of the sky at the desired angle.

#### FOREIGN NEWS AND NOTES.

**A Suggested New Printing Process.**—M. Léon Vidal, the editor of the *Moniteur de la Photographie*, suggests the use of a grained glass screen as the basis of a new method of printing. The tendency of modern photographic work has been towards the imitation of engravings or water-colour drawings. M. Léon Vidal thinks that those in search of novel effects might find it worth their while to make a positive from an original negative, and then a second negative through a grained screen. A grained print could thus be produced by the gum-bichromate, carbon, or any other process. Its characteristic would be that of a crayon drawing upon rough paper, and it is possible that the process might lend itself very effectively to three-colour photographic printing.

**Reduction of Bromide Prints.**—P. von Jankó recommends, in the *Photographische Rundschau*, a bath composed of—

Saturated alum solution .....	50 parts.
Four per cent. thiocarbamide solution .....	50 "
Acetic acid .....	1 part.

The prints should be immersed in the solution and rocked until the necessary reduction is effected. The process is slow enough to enable the operator to stop the right moment. The prints should be washed in several changes of water, which should succeed each other rapidly at first, to remove traces of the reducer and stop its action.

**Sensitising Plates for the Lippmann Process.**—In the *Photographische Correspondenz* Professor Valenta refers to the difficulties of colour sensitiveness. The gelatine film for mixed colour work must be thin, and, as this limits the latitude of exposure, the difficulty of obtaining good results is considerably enhanced. The colour sensitiser is an important factor in the problem. In proportion to the difference in sensitiveness for red, yellow, and blue, the difficulty of determining the correct exposure increases. The ideal should be a panchromatic plate; but, as this is not to be had, suitable sensitisers, that will give the nearest approximation, should be used. Cyanine and chinolin red have been recommended by Lippmann, and cyanine terythrosine by Krone. Cyanine is a very useful sensitiser for orange-yellow, but yellow-green and greenish-blue flag, and the action in the blue is many times more active than in the red. The addition of chinolin red overcomes the first of these difficulties, and erythrosine will reverse the relation between yellowish-red and green. It is therefore necessary to find a dye that will give equal sensitiveness for red or orange-red to blue-green. If the action in the blue should still be excessive, it may be controlled by use of a pale yellow screen. A dye of suitable character should yield a broad and rather vigorous band from C to E. Valenta finds from experience that glycin red is suitable, and it may be had from Kinzelberger of Prague. This dye renders green almost as well as blue, and the band extends from B $\frac{1}{2}$  C beyond  $\delta$ . It is also fairly sensitive. By adding 12 to 14 c. c. of glycin red (1 in 500) to each 100 c. c. of the emulsion described in Valenta's work, *Die Photographie in Natürlichen Farben*, very good results are obtainable. Lippmann has recently changed his method of preparing the emulsion, and now adds to a solution of gelatine, water, and bromide of potassium, very finely powdered silver nitrate. Emul-

sions thus prepared give very clean images and are very fine in the grain, but, after making comparative experiments, Valenta does not find the new formula better than that given in the work mentioned above.

**Brasswork.**—The *Photographische Chronik* gives the following formula for changing the colour of brass to a golden hue:—

Sodium hydroxide .....	5 grammes.
Milk sugar .....	5 "
Water .....	150 c. c.
Sulphate of copper .....	1 gramme.

The first two ingredients should be dissolved by heat in the water, and the sulphate of copper then added. Filter the solution and let it cool. The brasswork should be perfectly cleaned with an alkali, and immersed in the solution for a minute.

**Small Negatives.**—The *Deutsche Photographen Zeitung* publishes an article in which the advantages of small apparatus for the tourist are very clearly and forcibly enunciated. The favourite Continental sizes are 9 × 12 and 13 × 18 cm. These are both rather larger than our quarter and half-plate sizes. The *Deutsche Photographen Zeitung* recommends the dimensions 9 × 12 cm., also a current Continental size, and points out the gain in portability and speed of exposure. With a small size the amateur will not find the finest modern lens a very expensive luxury. The cost of plates is reduced to a minimum, and the fineness and depth of definition of the lens will enable him to make enlargements that will compare favourably with large direct pictures. Considering the ubiquitous nature of the English tourist, it would be a great boon if international sizes for plates could be adopted.

#### DEVELOPING PARTLY PRINTED GELATINE-CHLORIDE PAPER.

"Mr method," says Mr. Albert Hahn in the *American Journal of Photography*, "is that of Mr. William J. Wilson, who has succeeded in producing the most perfect results with gelatine-chloride papers—by development.

"The first point is to consider what is the minimum amount of exposure necessary for after-development. A faint image of the darkest parts of the subject should be visible about the degree necessary for platinum paper exposure.

"All the operations may be performed with dull gaslight.

"Incandescent gas or electric light may be used in place of sunlight for printing, an image being produced sufficiently intense for development in about fifteen minutes. A little over-exposure is not serious.

"After exposure, immerse the prints in a solution of potassium bromide, ten per cent. solution. This converts everything into bromide of silver, which is not so liable to fog under development as the chlorides or other silver salts.

"Five or ten minutes in the bromide is sufficient.

#### DEVELOPER.

##### A.

Hydroquinone .....	300 grains.
Eikonogen .....	120 "
Water .....	50 ounces.
Sulphite of soda .....	1 ounce.
Sulphuric acid .....	1 drachm.

##### B.

Carbonate of potassa .....	2 ounces.
Water .....	50 "
Bromide of potassium .....	120 grains.

"Mix the solution in about equal proportions, and add a drachm of gum-arabic solution (1 ounce gum, 1 pint water).

"Stop developing when the finest detail just begins to show, as there is a danger of carrying development too far. The image in the developer looks less dense than it is in reality, so that some judgment is needed to determine when to stop.

"After development, place the print again in a one per cent. solution of bromide of potassium, and wash for five or ten minutes in running water.

"Tone in the usual toning solutions if the colour obtained is not just what is desired."

## THE PERMANENCY OF PLATINOTYPE PRINTS.

An article appeared in one of the photographic papers not long ago, in which the writer thereof contended that prints made by the platinotype process were as liable to change as silver prints; in other words, that platinotype prints were not permanent. Photographers for some years past have been in the habit of regarding this process as the most permanent one on which they could make their prints, and it is to try and show that this process, if properly worked, will yield permanent prints, in the ordinary sense of the word, that this article is written.

It must be admitted that prints by any process, if the well-known rules for working them are not carried out, will alter; but in a silver print the actual image alters and deteriorates, whereas it is only the paper support, and not the platinum image, which alters in platinotype prints.

To prove this, let a platinum print, which has turned yellow, and whose image has turned a rusty brown colour instead of the pure black characteristic of the process, be placed for a few minutes in the following solution:—

Chloride of lime .....	2 ounces,
Carbonate of soda .....	1½ "
Water .....	20 "

and, when removed, the print will be just as good and brilliant as when it was first made, thus showing that the image itself was unaltered. It is advisable after this bath to treat the prints in a weak hydrochloric acid bath for a few minutes, and then wash as usual.

Now, surely this proves that the apparent deterioration of the print was only due to the acid which was left in the paper turning the paper yellow, and so causing the print to look as if it had faded. The actual image is not altered in the least, and from this it may be fairly said that, provided means are taken to rid the paper from injurious matter, the prints may be considered absolutely permanent.

After development it is necessary to pass the prints into three acid baths for a period of five minutes each, composed as follows:—

Hydrochloric acid .....	1 ounce.
Water .....	60 ounces.

Or, if preferred, citric acid may be used:—

Citric acid .....	1 ounce,
Water .....	10 ounces,

After this the print must be washed in plain water for about ten minutes, and then immersed in—

Carbonate of soda .....	1 ounce,
Water .....	20 ounces.

for five minutes, after which a final washing for ten minutes in water will complete the operation. This soda bath is intended to neutralise the acid in the pores of the paper.

If these very simple instructions are carried out, the platinotype worker will not be troubled with changing prints, but will be sure of prints which will remain things of beauty and a joy for ever.

E. W. HAWES.

## DARK LIGHTING.

PROFESSOR B. W. WOOD, of Madison, Wisconsin, writes to *Nature*:—

"I have been greatly interested by some photographs showing the rare phenomenon of dark lighting, which have recently been sent to me. So far as I know, the only explanation that has ever been offered to account for them is photographic reversal, due to extreme brilliancy. This appears to me to be wholly out of the question for two reasons. In the first place, a dark line on the picture, resulting from over-exposure of a very brilliant line, would be surrounded by bright edges, due to the lesser photographic action in the halation region. This is never present so far as I know, the dark flashes being minute black lines ramifying from, or in the neighbourhood of, the main discharge. Secondly, from what evidence I can gather, the dark parts of the flash are not those which appear most brilliant to the observer. Mr. Jennings, of Philadelphia, who in 1890 secured a remarkable picture (reproduced in *Photographic Times Annual*, 1891) showing a very brilliant flash with countless dark flashes covering the sky around it, tells me that the appearance to the eye was a brilliant white discharge, with fainter rose-coloured ramifications, the latter developing in the negative or rather positive, as dark flashes.

"Some years ago it occurred to me that a dark flash might be produced by a preponderance of infra-red radiations, which, as Abney has shown, undo the work of ordinary light on the plate. If we had a form of discharge capable of giving off very little actinic light and an abundance of infra-red light, it might come out dark on a feebly illuminated background. This is, of course, a very wild guess, with nothing to substantiate it; but the dark flash appears to be a reality, and a poor hypothesis is perhaps better than none at all. I have recently thought that the phenomenon might perhaps be explained in another way.

"We have a flash which appears darker than the sky behind it. It is inconceivable that the discharge could render the air in its path opaque, in the ordinary sense, to white light. But the light which illuminates the sky, in the case of these pictures, is not daylight, but light coming from another flash, that is made up of wave-lengths corresponding to the periods of vibration of the dissociated matter in the path of the discharge. Now, may it not be possible that in the dark flash we have a discharge, weak or nearly wanting in actinic light, which, however, renders the air in its path capable of absorbing to some extent the radiations of the wave-lengths which come from the bright flash?

"Such a flash might possibly appear dark on a background feebly illuminated by light, exclusively of these wave-lengths; in other words, may we not have in the path of the dark flash dissociated molecules, radiating but feebly, and capable of taking up vibrations of periods similar to their own, coming originally from a simultaneous brighter discharge?

"It might not be impossible to reproduce the phenomenon by photographing a spark in front of a light background. Sparks are almost always taken against a black background, which would account for the absence of dark flashes in pictures of artificial discharges. A heavy main spark with lateral branches would seem the most suitable kind to employ.

"The best method of attacking the problem experimentally, it seems to me, would be a search for selective absorption in a partially exhausted tube.

"If the source of light were continuous, any absorption would be unnoticeable unless persisting for some time after the discharge (which is unlikely), for the time between successive discharges is great in comparison to the actual duration of one of them. Even in the case of so-called continuous discharges produced by high potential batteries, the discharge is often, and may always be, intermittent in character. The source of light should then be of no longer duration than the discharge occurring in the gas the absorption of which is to be examined.

"I can think of no way of producing a white or continuous spectrum source of as short duration as, and contemporaneous with, the discharge in the tube, but by employing two tubes differently excited, the one as a light source, the other as an absorption tube, some results might be obtained.

"Professor Trowbridge found that an Argon tube emitted a blue light or red light according to whether it was illuminated by means of an oscillatory or non-oscillatory discharge.

"By using the blue tube as the source of light, and the red tube as the absorption tube, the two being arranged so as to be illuminated simultaneously, it might be found that the red tube had the power of absorbing, to some extent, the blue radiations from the other.

"I hardly think results would be obtained, but the experiment seems worth trying.

"A picture taken by Mr. H. B. Lefroy, of Toronto, sent to me by Mr. Lumsden, Secretary of the Astronomical and Physical Society of Toronto, has some very curious appearances. There is an exceedingly brilliant flash running down the centre of the plate, illuminating the sky quite brilliantly in its neighbourhood. In its immediate vicinity, though not joined to it in any way, are innumerable dark, thread-like markings, which in places seem to cross each other, forming meshes. Mr. Lumsden assures me that the testimony of all photographic experts who have seen the plate is to the effect that markings of that description could only be produced in the exposure—that is, they are not due to faults in the film or the results of imperfect development. The fact that they are found only in the immediate vicinity of the bright flash is additional testimony in the same direction. These markings are wholly different from any that I have seen, not having the form of branched flashes. Something in their resemblance to photographs of sound-waves, started by a spark, which I have recently made (see *Phil. Mag.* for August), suggested to me that they might possibly be due to the illumination of the sound-wave, due to a powerful discharge by a second discharge. Under ordinary conditions, that is, with a uniformly illuminated background, such waves would, of course, be invisible, but conditions might possibly arise, due to the proximity of black clouds, under which they might show, a sort of 'Schlieren Methode' on a large scale. I have not attempted yet to plan an arrangement of clouds which, by acting as screens to light coming from certain directions, might render visible a region of the air in which the optical density underwent a rapid change.

"Mr. Lumsden's picture shows very black clouds irregularly distributed and in close proximity to the flash.

"The idea of a photograph of a thunder wave is a pleasing fancy, at all events.

"It seems to me that it will be impossible to formulate even a reasonable guess as to the cause of these dark flashes until a good many pictures are brought together for comparison and as much testimony as possible secured as to the appearance of the flashes to the eye. Personally I have seen very few of the pictures, and never the original negative.

"My intention in writing this letter is not so much to advance theories accounting for the phenomenon of the dark flash as to re-awaken an interest in the subject, and bring out ideas from persons qualified to treat the matter."

### "PAINTERS WHO HAVE INFLUENCED ME."

On Wednesday evening, the 13th inst., a large number of the members and friends of the Leeds Camera Club foregathered at the Club Rooms, Grand Restaurant, Boar-lane, on the occasion of the opening lecture of the session, to hear Mr. J. Craig Annan, of Glasgow, lecture on the above interesting subject.

The lecturer, who is a well-known exhibitor at all the leading exhibitions, had been induced by the enterprise of the Club to give the address, which is the first delivered by Mr. Annan in England.

The President, in introducing the lecturer to the audience, said that his duty that evening was a very pleasant one. Mr. Annan's works were well known to them, and no doubt they had all seen and admired them; he was working in the same direction as themselves, and anxious to help others to the same position to which he had attained. He would show them that by artistic tastes one could make a photograph something more than a mere machine-turned-out article. On behalf of the Leeds Camera Club, he had great pleasure in asking Mr. Annan to give them his lecture.

Mr. Annan, who was heartily received, commenced by stating that, when asked to give a lecture on painters, he had promptly replied, without considering what such promise involved. He had given the subject the consideration of his leisure moments, and the results had been a revelation to himself. It was not to be expected that all, if, indeed, any of them, should feel as he did on the subject, as it was a matter of personal sentiment, and one on which they each could feel for themselves.

At first glance of the subject he was overwhelmed with a formidable array of masters and nationality, in whose works he took interest and delight: Rembrandt, with his marvellous expressive powers and mastery of light and shade; Frank Hals, overflowing with the love of life, suggesting to the observer that his greatest works are but play to him—behind all he had an enormous force which he could exert if he chose to do so. The Italian painters—Titian, Tintoretto, Botticelli, and others—were touched upon, and many other famous works alluded to.

Passing on to Germany, we had the master of Nuremberg, Albert Dürer, who surprised us with the variety of the arts he excelled in, and his superiority in every one of them. Then, in later days, and in our own country, the group of masters we had had in Sir Joshua Reynolds, Gainsborough, Romney, and Raeburn, and before them, though not precisely of this country, Sir Anthony Vandyck, courtier as well as painter, his pictures full of that grace, and strength, and dignity which befit those who surround a throne; whilst a century before him was Hans Holbein, whom, in the opinion of the lecturer, it would benefit photographers most to study. Adverting to the fact that he had not alluded to the famous landscape painters, he said, on reconsideration he came to the conclusion there was no omission, his greatest pleasure being the study of those masters he had named, and, much as he could enjoy and delight in the works of Constable, Turner, and their contemporaries, yet the former had most influenced him.

The necessity of photographing a landscape as it actually is, without the power of selecting the point of view, and the impossibility of subduing any portion of the subject as regards its form and shape, was most exasperating to the photographer who had revelled in the grand, massive compositions of Constable or the delights of Turner. In portrait photography one had the subject more under command; the choice of subject, light, dress, and pose might all be made by the photographer, and, while it could be said that a photographic portrait seldom did approach, and possibly never could equal, a masterpiece of painting, yet their hopes led them to trust that, when some real master appeared, photographic portraits might be produced which would take a place among the world's art treasures for all time.

As students of photography, therefore, they must select from those various qualities in the works of painters those compositions it was possible for them to embody, and consider in which of those painters the qualities were most evident, and from which, therefore, they were most likely to draw inspiration.

Another point was, how much they should allow themselves to be influenced by any master, and a line between influence and mere imitation must be drawn. One frequently read in the criticism of exhibitions that, in the opinion of the reviewer, a certain work was manifestly produced under the influence of a certain painter, and the inference intended to be taken was that the work was to be deprecated on that account; but, in considering the question calmly, as he did, if the producer had been sufficiently influenced by certain great masters, and had absorbed and followed the intention of that master, then he declared that it was a credit and an honour to have been able to follow to such an extent that his work is a digest of the master's and not a mere superficial imitation. If it is a copy only, then the incompleteness of the work would be stamped on it and would condemn its producer; but to be influenced in a legitimate fashion was quite another matter, for without influence they would be back among the cave dwellers, and the most daring genius amongst them would be scratching a rude resemblance of his dog upon the doorway of his dwelling.

Genius has been described as the art of taking pains, and he advised all of them who aspired to introduce art into their pictures to miss no opportunity of studying the work of the masters. If they could not see

the original works, reproductions were excellent and cheap, and he counselled them to study and observe to their utmost capacity the spirit of the authors, without the slightest fear that by doing so they would become plagiarists. If they had the proper receptive faculty, an impression would be made on their minds which, though it might appear to pass away, would only lie fallow for a time. It would enable them to introduce ideas which would otherwise have escaped their attention, and enable them to produce unconsciously a successful picture which was their own and yet inspired by another. As an illustration, he might mention a certain experience of his own portrait of Miss Burnett, produced in 1893, which was to a great extent influenced by a picture he had seen, he could not exactly say where, of Erasmus, by Holbein, and but for the influence of this or some such picture he was positive Miss Burnett's portrait would not have been produced. Having explained the grounds for his preferences, he thought no painter had interested him more than the one he had alluded to—Hans Holbein—whose works were widely scattered in this country, but reproductions could frequently be met with, and from a photographer's standpoint they were as beneficial as the pictures. The magnificent collection of drawings in Windsor Castle was an education to any artist.

Holbein could hardly be said to be a member of any particular group of painters, but he made his entrance on the stage of life at one of the most interesting periods of history, at a time when all the nations of Europe were awakening from the lethargy of the dark ages. His earliest achievements were considerable, and his originality consisted not in eccentricity, but in the simple breaking away from all convention and making a close and intelligent study of nature. The lecturer traced the chief events in the career of Holbein and mentioned the more important pictures painted by him, remarking that in most of the pictures exhibited on the screen the backgrounds were absolutely plain, thus showing up the beauty of the figures thereon. As a photographer he could tell them it was very much easier to make a respectable picture with a fancy background than to make a real fine picture with a plain background. To him it was always a sign of weakness to see a pictorial background. He concluded by expressing the hope that what he had said might help them in the study of pictures and also in their photographic work.

Mr. Councillor Howgate, in proposing a vote of thanks to the lecturer, expressed the pleasure it had given him to be present and his gratification that a Leeds audience had been privileged to hear Mr. Annan, a lecturer who was so ably qualified to deal with his subject.

Mr. Bissington seconded, and Mr. Gosh supported the vote of thanks, which the lecturer suitably acknowledged, and the proceedings terminated.

### THE ALLEGHENY OBSERVATORY OBJECTIVE.

MR. J. A. BRASHEAR supplies the *Scientific American* with some particulars regarding the new Allegheny Observatory and the glass which he is to make for them. He says: "The old Observatory, in which Professors Langley and Kuhn did such good work, became unfitted for modern research; first, on account of its rather meagre equipment, but, what was far more important, the city has so encroached upon it that the atmosphere is usually vitiated by the smoke from houses, mills, &c. As Chairman of the Observatory Committee, I first had the good fortune to secure a splendid site in the very centre of the new park given to Allegheny City by its generous citizens, which is situated beyond the smoke environments. The place set apart for the observatory is a hill in the centre of the park, 552 feet above low-water mark of the Ohio River and about 1200 feet above sea level, and it is so situated with reference to the two cities of Pittsburgh and Allegheny that the prevailing winds give us a practically clear atmosphere. It is a fact, however, that a small amount of smoke diffused through the atmosphere contributes to steady definition in solar work, to which, I think, we shall devote most of the time of the new Observatory.

Plans for the new Observatory are now nearly complete, Professor F. L. O. Wadworth, the new director, having devoted many months to a careful and critical study of the detail of the building and instrumental equipment, and, if the plans are carried out to the fullest extent, we shall have an Observatory for astro-physical research second to none in the world. Not the largest telescope—we are not after that—but a complete equipment for work in the domain of the new astronomy.

Our plans now are to have a thirty-inch clear aperture telescope, the discs for the objective of which have already been ordered from Mantois, of Paris, and will be ready for us about the first of the year. A large reflecting telescope, perhaps of not less than a thirty-six-inch aperture, will be constructed for spectroscopic work. A thirteen-inch refractor will be erected and equipped solely for the use of the citizens, or, in other words, a free observatory for the use of the higher classes in the public schools, and any and every one desiring to see the "beauties of the skies." This has always been a hobby with me, for well I know, when a boy, how I would have given all the little I had to look in a telescope. But I am getting off the track. In addition to the telescopic equipment, we expect to have an immense siderostat, by which we can use the great objective for projecting the sun's image on the slit of the large spectro-heliograph, which will, by this arrangement, not have to be carried by the eye end of

the large telescope, but will remain stationary in a specially constructed underground apartment. The entire basement of the Observatory will be fitted up for correlated research, i.e., especially in the domain of solar physics, and the beam of light from the great siderostat will be brought down to the basement, and by suitable mirrors made available in every department of the Observatory. The building will be provided with a sixty-foot dome, a thirty-foot and a twenty-six-foot dome. The architectural design of Mr. T. E. Billquit has been accepted. It is classic in style, and will look very beautiful on the hill in the park. It will be visible over an area of perhaps fifty square miles.

## PHOTOGRAPHY OF THE STOMACH.

[Scientific American.]

DR. MAX EINHORN, of New York city, made a communication to a medical journal some seven years ago regarding "ga-tro-diaphany," in which a miniature Edison lamp, in a special mounting attached to a soft rubber tube containing a wire, was introduced into the stomach, so that an examination can be made of it. This method was called "ga-tro-diaphany," as the stomach became translucent. The object of this device was to show the size and situation of the stomach to the eye and also to recognise tumours or other gross anatomical changes of the anterior wall of the stomach. This was, of course, a different apparatus than the "polyscope," which is used for looking into the stomach, and was not intended to replace any such device. It has been found to be of considerable value to surgeons.

In the same paper Dr. Einhorn described a camera for photographing the interior of the stomach; but, owing to technical difficulties, the camera was not constructed by Dr. Einhorn. Such a camera has, however, been perfected by Dr. Fritz Lange, of Munich, Germany, on almost the identical lines given by Dr. Einhorn.

The camera is a marvel of compactness, and is constructed on exactly the same principles as all cameras for taking moving photographs, although, of course, there is no attempt made to combine them so as to project the actual operations of the stomach. The camera itself is swallowed by the patient, and it contains a small electric lamp for illuminating the walls of the stomach. A photographic film twenty inches long and a quarter of an inch wide is wound at the bottom of the camera. One end of the film is fastened to the cord, which runs freely in the tube. When the cord is pulled, the film is drawn slowly past the lens. The cord and the conducting wires must, of course, be swallowed with the camera itself. When the camera reaches the bottom of the stomach the surgeon begins to pull the cord, which runs the film past the lens. The electric light is then turned on, and, after the sensitive film has been impressed with the image, the current is turned off and another section of film is brought into play until the requisite number of pictures have been obtained, then the entire apparatus is withdrawn from the stomach of the patient and the films are carefully developed and enlarged.

## A MACHINE FOR CUTTING PRINTS.

MR. CHARLES HENRY WORTHEN, of Taunton, Massachusetts, U.S.A., who has invented a machine for this purpose, says, in his Patent specification, that photographic prints must have clean cut, sharply defined edges, necessitating the use of an extremely keen trimming cutter, and the print in course of trimming is placed commonly upon a glass or metal support to aid in securing the desired smoothness of edge.

Inasmuch as each print must, as a rule, be trimmed separately, the keenness of the cutter wears off very rapidly under the condition noted, and the cutter must be sharpened frequently, with considerable annoyance and no small expense.

To obviate the attrition of the hard surface of the metal or glass upon the cutter, a trimmer has been provided in which a rotary cutter, supported from above by a trolley-like arrangement, and rotated positively by a belt, is moved along the end of a board, over which projects the print to be trimmed; but the trolley support bends under the pressure of the operator's hand, the cutter gets below its proper cutting position, and, adding to these the absence of suitable supporting and clamping means for the projecting portion of the print, the result is that the latter is frequently crimped over and chewed off instead of being cut properly.

Mr. Worthen proceeds: "I have instanced the difficulties of trimming photographic prints properly, as typical of the severest requirements to which a successful and durable cutting device is subject, and my invention has for its object the production of a cutting device which shall meet these requirements fully, and be perfectly adapted for use as a photographic print-trimmer, but I contemplate its utilisation in any class of work for which it may be qualified by the improvements constituting my invention.

"A designates a work support taking the form, in this instance, of a common type of trimming board, and which may be of any suitable material, preferably wood for the sake of lightness, and, if of wood, provided preferably with a cutting edge, B, which may conveniently be

constructed of a bar of metal inlaid flush with the surface of the support and having a longitudinal surface groove, one wall of which constitutes the 'edge.'

"The work support may be, and preferably is, provided with one or more suitable guides, a, slightly raised above its surface and its shape and proportions may vary as desired or found convenient.

"In accordance with my invention, a travelling cutting member is provided having a cutter with a straight edge to run along and co-operate with the wall or 'edge,' B, and an inclined or bevelled abutment is also provided parallel with the 'edge,' B, the travelling member having a bevelled portion to ride along the bevelled portion of the abutment, which latter is inclined toward the 'edge,' B, so that the effect is that, when the members are in operative relation, and the cutting member is being run along the edge of the abutment, it tends constantly to slide down the bevelled portion of the latter until the straight edge engages the fixed 'edge.'

"The disposition of the bevelled abutment and the co-operating bevel on the travelling member may be varied somewhat, but I have found a convenient arrangement thereof to be afforded by forming the bevel of the travelling member on the cutter itself, and, in the instance illus-

trated, have made use of a rotary cutter, c, mounted for convenience of manipulation in a carriage, D, of desired or suitable contour.

"The form of bevelled abutment which can be used most conveniently with a bevelled rotary cutter of the type illustrated is shown at E, being closely adjacent the fixed edge, and being formed of a piece of sheet metal, or other suitable material, which is preferably hinged or pivoted at its rear end or edge on an axis parallel with the fixed 'edge' to permit the abutment to be swung upward from the latter.

"To prevent undue protrusion of the abutment above the support, it is bent preferably, as at F (see fig. 3), and for the sake of stability may be mounted in suitable bearings, G, on the support, A, being shown in this instance as lugs bent up from a metal plate, H, secured to the board, A, by suitable fastening means, as the screws, I, these lugs receiving a spindle, J, which serves as the axis of the abutment.

"When thus constructed, the abutment may be utilised as a clamping member or means to clamp the edge of the photograph, print, or other work adjacent the fixed edge, and such a clamp is particularly desirable when use is made of a bevelled rotary cutter, inasmuch as such a cutter tends constantly to cut in a circle, and the print can be firmly held to prevent it from being cramped under this circular action of the rotary cutter, which otherwise would be communicated to it.

"The use of the bevelled abutment as a clamping member is facilitated by the co-operating bevelled surfaces, as will be readily understood from fig. 3, where it will be seen that downward pressure upon the carriage, D, will be communicated through the cutter, c, to the abutment, E, and at the same time that said bevel is causing the straight edge, c, to engage

firmly with the fixed 'edge,' *n*, the cutter is forcing the abutment to clamp the edge, *h*, of the print or other work, *n*, against the surface of the work support, holding it firmly during the cutting operation.

"It will be understood readily that by this arrangement the clamping pressure is applied to the member, *x*, automatically at the point and time when it is most needed, that is, just as the cutter, rotary or otherwise, is approaching the cutting point, the effect of the pressure on the member, *x*, of course, extending for a little distance before and behind the point at which the cutter may be at any given instant.

"The carriage, *v*, may be of any suitable form, and the cutter mounted therein in any convenient fashion, in this instance the carriage taking the form of a block, in a recess, *d*, of which is mounted the cutter, *c*, on a journal, *c'*, entering suitable bearings, *d'*, of the carriage, said bearings being illustrated as metal plates with holes, *d''*, at the end of the journal and attached to the carriage by suitable fastening means, as the screws, *d'''* (see fig. 4).

It is within the spirit of my invention to use the cutter without any guide or track other than the fixed edge and abutment, but it may be found convenient to use a guide rail or track, and accordingly I have illustrated for use, when desired, a rail, *m*, supported above the surface of the work support to permit passage of the work thereunder, and having a contour suitable to co-operate with the carriage, *v*, such co-operation being effected, in the instance illustrated, by an undercut groove, *m*, in the rail, into which enters an upward projection, *d'*, from the carriage (see fig. 2).

"The rail, *m*, may be supported in desired position by any suitable means, and one convenient form of such means is shown in the shape of risers, *a'*, secured to the work support by suitable fastening means, as screws, *a''*, the latter preferably passing through slots, *a'''*, for the sake of adjustment, while similar adjustment may be provided for between the rail, *m*, and the risers, *a'*, by slot and screw connexions, *a'* *a''*.

"The carriage, *v*, may be grasped by hand and operated to and fro along the cutting edge, or may be operated by any other suitable means.

"As in accordance with my invention, the travelling member co-operates with the clamping member to operate the latter to clamp the work to the work support during cutting traverse, so also, in the preferred form of my invention, it is adapted to operate the clamping member to give clearance to the work for insertion or withdrawal.

"Any suitable means to effect this end may be adopted, and I have illustrated one form of construction for the purpose, comprising a lever, *p*, fulcrumed at *p* on an upturned lug or projection, *f'*, of the plate, *f*, one arm of the lever being extended into position to engage the clamping member, *m*, while the other end is extended into, and near the end of the path of, the travelling cutting member, so that, when the latter is brought into the position shown in fig. 5, the lever is tipped and raises the member to give clearance for insertion or withdrawal of the work.

"One of these levers or equivalent means may be provided, if desired, at each side of the clamping member, as illustrated.

"Considerable variation in the construction and arrangement of parts may be made without departing from the spirit of my invention, and I do not limit myself to the exact construction illustrated and described otherwise than as set form in the claims."

#### EXTRACTING AND ENLARGING SINGLE FIGURES FROM GROUP NEGATIVES.

It frequently falls to the lot of most photographers to undertake the enlarging of a small head or single figure which is contained in a negative or ordinary print, and is surrounded by other figures, such as are commonly seen in groups, and it often happens that such figures, by reason of their surroundings overlapping part of the same, cause no small amount of difficulty to a photographer when attempting to extract the figure for the purpose of future enlargement.

In all cases where the original negative is obtainable, there is no question as to the advantage of working on the same in preference to endeavouring to gain similar ends by manipulating a print made from such negative; but it often happens that the original negative is not forthcoming, and then there is no alternative but just to do the best with what material exists, such as a simple silver print.

Work of this description, as a rule, is seldom required from pictures that have been made within a recent period, but almost invariably fall to be conducted from photographs taken many years previously, and which are printed on albumenised paper, the texture of which is far more liable to offer difficulties than would be the case where they are printed on the more modern samples of Aristo or highly glazed gelatine or collodion surfaces.

A striking example of this sort of work has recently come under my observation, and which has proved of considerable interest in more ways than one. In the first place, the picture in question was made by means of wet collodion so far back as the year 1865. This was printed at the time on a sample of single albumenised paper, and, notwithstanding that this silver print has been subjected to the usual exposure in a family

album, at the present moment it is absolutely free from any symptoms of fading, and is a strong proof of the permanency of a well-executed silver print by means of single albumenised paper.

So far back as the year 1865, the taking of groups, especially inside studios, by means of wet collodion was generally done in small dimensions, and therefore each of the figures (or faces, rather) is very small in the picture to which reference is being made; these probably do not exceed a quarter to three-eighths of an inch, the whole group of eight people being printed in *carte-de-visite* size.

We hear a good deal nowadays against the permanency of pictures printed by means of silver. Yet here is an instance where a print is to all appearances as fresh to-day as it was thirty-four years ago, and is a striking tribute to the work turned out by the photographer whose name appears on the back of the card.

Somewhat recently the writer had the good fortune of spending a pleasant time with one who is now without doubt the oldest photographer in the West of Scotland, and who was an intimate friend of the brothers Mactear, and working alongside of them in the very first days of Daguerreotype and wet collodion. When speaking on the question of permanency, this gentleman remarked, "Oh, before double albumenised paper was known fading was never thought about." But with its introduction a sad change was brought about, and he now can point to proofs innumerable of his assertions, maintaining that all his prints dating back from the earliest days of silver printing are quite permanent, but those printed in after-years seldom stood at the outside beyond six or seven years at the best.

There is no doubt, however, that the grain of the paper is liable to cause more trouble when such small heads have to be enlarged from prints on single albumenised samples, and to avoid this grain, when work of this description has to be done, several methods have from time to time been advocated. One of these is to apply to the surface of the print a coating or wash of water-colour pigment, blocking out all the surroundings of the head it is desired to extract. Ivory black and Chinese white are, when mixed, suitable pigments to employ for this purpose, any depth from black to a light grey being easily obtained; the application of such a pigment to the face of a silver print will, with care, cause no injury, and, even in cases where the object or head is very small in size, there is no difficulty to trace round the outlines of the face with the aid of a finely pointed sable pencil. When this first operation has been successfully accomplished, a negative in slightly enlarged form is made in the usual way, and this is subjected to a very thorough retouching, which will, if properly done, get rid of any coarseness which is almost certain to manifest itself. Enlargements made from negatives produced in this manner yield good results when finally worked up in black and white.

Another method which also yields excellent results is sometimes possible of accomplishment, having the further advantage of not requiring the application of any pigment to the surface of the print. This is done by providing a cut-out mask that just fits nicely around and suits the shape of the head that is being extracted; but how is any one to provide such small-sized masks as from three-quarters of an inch or thereby? Such masks are certainly not a marketable commodity, but larger sizes are, and any stock of lantern masks can be utilised for the purpose. When it is desired to mask off, say, the head and shoulders of a figure in a group, a lantern oval mask having a white surface on one side must be procured—any dealer will supply them in various shapes, and, having obtained one that just suits the shape required, it should be placed against a piece of black velvet and pinned to a board—the white side out, of course; this is then photographed in reduced size on a slow lantern plate, and, if a small stop be used and the plate backed and developed properly, a negative will be produced having clear glass in the centre of the oval, and sufficient density around it to enable it being superimposed on the glass side of the negative which has been made from the paper print, and which it is intended to employ in the final enlargement.

In copying the paper print much may be done to keep back the grain of the paper by so placing the picture in the best light for the purpose. This may mean using a somewhat direct source of lighting, but in nearly every case it will be more or less noticeable, and the negative, therefore, has to be skilfully retouched. In saying this I am quite cognisant that there are those who dispute retouching in every shape or form, but my experience has taught me this, that any one who has to cater for the public taste and to earn his bread and butter by means of photography cannot do without practising it in nearly every subject and branch of work, and I should like to know what professional can honestly say he never resorts thereto.

The fact is, modelling is an absolute necessity in nearly every branch of photography, and especially is this the case in the work referred to, and not only must the modelling be applied to the negative, but the final enlargement will also be most wonderfully improved by its aid also.

It has been said that, in all cases where the original negative is obtainable, it is much to be preferred that it should be employed instead of a print from it. Of course, there will be no need for anything like the same amount of modelling when the original negative is available, and very probably no retouching of any kind will even be required, all that is necessary being the provision of some means to shield off objectionable surroundings to the head, and even in this event the work

can be accomplished without manipulating the negative at all. In many cases this is the most desirable method to follow, simply because it does away with any tampering with an original, and very possibly a highly prized, negative, so that, in cases where the masking can be effected on the surface of the enlargement, it is better to arrange for it than to do so on the face or glass side of the negative.

To mask out objectionable surroundings to an enlarged head is by no means a difficult operation when proper materials are at hand for the purpose and the system employed in enlarging permits of it.

In large sizes, special cut-out masks will be required, but in smaller sizes any ordinary paper cut-out mount may be employed, provided the edges of the cut-out are true, so that, having selected the cut-out aperture, which suits the size and shape of the head and shoulders of the figure when it is projected in enlarged form on the copying board of the easel, and having carefully adjusted the focus of the enlargement, the sensitive paper is placed in position, and by means of the non-actinic cap of the lens the image is projected on same. The mask is then fixed in position over the sensitive paper and the exposure made in the usual manner.

The services of a good printing frame may be utilised for holding the paper and cut-out mask *in situ*, and, when the enlarging is accomplished by daylight, it is easily slipped into its proper position on the easel, and much comfort experienced in executing enlargements in this manner.

The vignetting of enlarged heads can also be accomplished by employing a suitable cut-out mount between the lens and the sensitive paper, arranging this at the proper distance in front of the easel, and, when the form and other conditions of the negative permit of vignetting being resorted to, there is no doubt is a very desirable method to follow. It must be borne in mind, however, that a few simple attachments will be required to hold the vignetter *in situ* during exposure. This may mean merely tacking the cut-out mask to a lath or flat stick, and nailing it on some support that will hold it steady during exposures, and the nearer it is placed to the sensitive paper the smaller the circle of light, and *vice versa*. But this is easily judged by pinning a sheet of white paper in the position the sensitive material is to occupy.

In using glass shields made in the manner suggested by copying white masks on lantern plates the utmost care will be required to obtain absolutely clean, clear results, and, if on development of the plate it is seen that the black velvet from over-exposure has caused a reduction of the sensitive emulsion at those parts, the negative should be treated to a local application of some reducer whereby such deposits are removed.

These glass shields are very useful, especially in cases where several enlargements are required from the same negative. By using these shields attached to the glass side of the negative every enlargement is produced in exactly the same form, and, if the same treatment is accorded each in exposure and development, there should be no appreciable difference between any of the results obtained by this method of shielding. With some of the other methods it is not so easy to get a number of enlarged prints all alike.

T. N. ARMSTRONG.

### THE LANGFIER STUDIOS.

SINCE their completion, four months ago, the studios of Messrs. Langfier, Limited, 23A, Old Bond-street, W., have been visited, we are informed, by some 1500 sitters, chiefly drawn from the aristocratic sections of society, and the Company's *clientele* is daily increasing. Theatrical group and portrait work, which was originally intended to form a prominent part of Messrs. Langfier's business, has been practically abandoned. The very fine quality of the portraiture which is produced at Bond-street has attracted a different and more remunerative class, and the result is that the Langfier studios are entitled to take rank amongst the leading photographic establishments of the day.

From a tastefully decorated entrance-hall the studios are approached by a lift, and the visitor speedily finds himself in a large reception-room, which is an art gallery in itself, showing as it does a very large collection of Messrs. Langfier's work. The studio, dressing-rooms, &c., are adapted for the most refined tastes—in a word, as the current phrase goes, everything is done in the best of style, and sitters, particularly those of the gentler sex, cannot fail to be pleased by the agreeableness of their surroundings.

For his services in connexion with the recently held bazaar in aid of the funds of Charing Cross Hospital, Mr. Langfier received the unique compliment of election to a Life Governorship of that institution. The Company's business is extending in several directions, and the production of photographic Christmas cards on a large scale is already receiving attention. Printing works are to be taken in the suburbs, and at an early date it is anticipated that one or two provincial branches of the business will be established. It is only six years since the Langfier studios in Glasgow were opened. During the few months that the principal centre of operations has been transferred to London, Langfier portraiture has won for itself very considerable renown, and the enterprise, skill, and energy at the Company's command give the greatest auguries for its future prosperity.

### THE LATE W. K. BURTON.

WE are sorry to have to announce the death of Mr. W. K. Burton, which took place on August 1, at Tokio, Japan. The deceased gentleman had for a considerable time past resided on the island of Formosa, and had there suffered from a malarial complaint, which probably was the indirect cause of his death. Mr. Burton was about forty-six years of age. It is a melancholy coincidence that his younger brother, Cosmo Innes Burton, at one time also a contributor to our pages, died a few years ago in the East, whither he had gone from Edinburgh to take up an official appointment.

W. K. Burton was the son of the late Dr. John Hill Burton, of Edinburgh, at one time Historiographer Royal of Scotland. As a writer on photography Mr. Burton first became prominent in the early eighties. Emulsion theory and practice supplied him with a fruitful theme for a facile pen. He owed much to the encouragement which he received from THE BRITISH JOURNAL OF PHOTOGRAPHY and its late editor, Mr. W. B. Bolton, for it was in conjunction with the latter that many of Burton's experiments were carried out on the old premises of the JOURNAL in York-street, Covent Garden. Indeed Burton, like many other prominent men of the gelatine era, traced the foundations of his position and influence to the opportunities given him by THE BRITISH JOURNAL OF PHOTOGRAPHY, with which he remained in occasional and sympathetic communication up till the spring of the present year.

An able and careful experimentalist, Burton was a luminous writer on most branches of applied photography, and his little beginner's book, at one time called the *A B C of Photography*, was one of the most successful text-books on the subject ever issued, as it has passed through numerous editions, and is still popular.

Sanitary engineering being his profession, Burton, early in 1887, left for Tokio, where, at the Imperial College, he was appointed to a Professorship. Before his departure he was entertained to a complimentary dinner organized by this JOURNAL, of which he had so long been a valued contributor. In Japan his interest in photographic matters showed no abatement, and his contributions to the periodical literature on the subject were always marked by sound doctrine and clearness of teaching. A useful set of exposure tables owed its origin to Burton, but his name can scarcely be said to be attached to any original work of first-rate importance. He was a perfect type of the painstaking and experimental photographer, with a happy gift of being able to transmit his knowledge to others. Perhaps he left England before his undoubted photographic abilities and instincts had reached their fullest fruition.

Burton's premature end will, we are sure, be deeply regretted by his many friends in Britain.

### SIGHT FOR THE BLIND?

WHAT degree of credence is to be attached to the following experiments and statements we must leave our readers to judge for themselves: The Central News is informed by Dr. Peter Stiens, the Russian electrician, that he has applied an electrical apparatus of his invention to several blind persons, and has made them able to see light and the shape of objects around them.

In the course of an interview with a member of the staff of the Central News, Dr. Stiens said:—

"I have been working on this invention for some years, and have every confidence now that I shall soon bring it to such a state of utility that blind persons by its aid will be able to see with their brains just as ordinary people see through their normal eyes. In a word, my invention acts in place of the eye."

Dr. Stiens then suggested that the interviewer should judge for himself, and the latter describes what happened as follows:—

Dr. Stiens took me into a small room and blindfolded me. He did this so effectually that not a ray of light reached my vision. All was absolute darkness. Then he lighted matches in front of my face, so close, some of them, that I could smell the burning sulphur, and could feel the heat of the flame near my flesh. But I could see nothing. Then he connected me with his apparatus. The blindfolding substance was not touched or altered in any way, but in place of the darkness there appeared a white light before me—a light that looked very much like the ordinary light of day. Then Dr. Stiens held up an object before me.

"What is this?" he asked.

"A pair of pincers," I replied.

"Quite right," answered the electrician; "and what is this? what shape is it?"

He now held up another object.

"It is round."

"Exactly. Now what can you see?"

"Only the white light."

"Exactly."

Then he switched off something and all was utter darkness again.

"I have taken off the apparatus and now you can see nothing."

"Exactly," I answered.

He took off my bandage and I found myself in the broad daylight again. "I will show you something else," he said. "Stand before this wooden partition."

I did so, staring at a blank expanse of wood, my eyes about six inches from it.

Dr. Stiens blindfolded me again, bidding me stand still, in the same position, before the wooden partition. Then he applied the electrical apparatus and I could see the white light in front of me as before.

"There," observed the inventor, when he had unbandaged my eyes, revealing the wooden wall in front of me, "you didn't see that light through the wood with your eyes—you saw it directly with your brain."

### PHOTOGRAPHIC CLASSES AT THE BATTERSEA POLYTECHNIC.

We append particulars of the classes in photography at the Battersea Polytechnic, which are under the direction of Mr. E. Senior.

*Elementary* (25 lessons) Mondays—Lectures, 7.30 to 8.30. Fees—Trade Students, 4s.; Amateurs, 6s.; per session. Practical, 8.30 to 10. Fees—Trade Students, 7s. per session; 3s. 6d. half session. Amateurs, 10s. per session; 5s. half session.

*Advanced* (30 lessons) Thursdays—Lectures 7.30 to 8.30. Fees—Trade Students, 5s.; Amateurs, 7s. per session. Practical, 8.30 to 10. Fees—Trade Students, 10s. per session; 5s. half session. Amateurs, 12s. per session; 6s. half session.

A reduction of 1s. per class is made to Members.

The Advanced Course prepares students for the City and Guilds examinations.

The new regulations of the City and Guilds Institute require students to pass a local practical examination before admission to the written examination in the ordinary grade.

The Photographic Department contains a large studio fitted with Joel are lamp and reflector, for photographic work at night; two commodious dark rooms, lit with electric lanterns, and fitted up with every convenience for work. The equipment includes an 8½ × 8½ studio camera and lens, a 10 × 8 copying camera, fitted with Zeiss lens, an electric light enlarging apparatus with ten-inch condenser, a complete set of carbon and platinotype printing apparatus, and a special camera for lantern-slide making, so that ample provision exists for practical work. The classes are primarily intended for trade students, but others are admitted upon payment of higher fees.

Students will be provided with necessary chemicals and apparatus free of cost, but must provide their own plates, sensitive paper, &c.

Students who desire to gain a thoroughly sound knowledge of the science connected with photography are strongly advised to join a chemistry class, and to attend the lectures on light.

*SYLLABUS.—Elementary.*—Lectures on principles of photography; the camera and detached parts; the dark room and fittings; use of camera; plates; exposure; lenses; developers; defects; intensifiers; printing and toning; practical work in dark rooms and instruction in taking and copying with electric light.

*Advanced Lectures.*—The studio; portraiture; lighting the model by daylight and electric light.

*The Dark Room.*—Illumination of, and methods for testing safety of light.

*Negatives.*—Exposure of gelatine plates under every condition of light, subject, &c.; use of exposure tables, meters, &c.

*Development.*—Nature of development; the various substances in use and their relative advantages and disadvantages.

*Intensifying and Reducing.*—Both wholly and locally; the preparation of gelatine emulsions; composition of and defects in gelatine plates.

*Optics.*—The construction and use of photographic lenses; testing lenses; preparation and use of colour screens for isochromatic photography; use of shades and instantaneous shutters; testing speed of shutters.

*Cameras.*—Various forms and their use; camera stands; testing cameras.

*Landscapes.*—Choice of position; direction of light, &c.; use of view meters.

*Printing.*—Printing in silver, carbon, and platinum, including vignetting; printing in clouds, &c.

*Toning and Fixing.*—Theory and practice of, with formula for various solutions.

*Retouching and Spotting.*—Mounting prints; theory and practice of the wet-plate process, both negative and positive.

*Elementary Photographic Chemistry.*—Simple test for ordinary photographic chemicals.

*Enlarging.*—General principles involved, and calculations in enlarging or reducing to scale.

*Practical Classes.*—Instruction will be given in negative making, contact printing on bromide paper, silver and platinum printing, general studio work, and lantern-slide making; wet-collodion process; single and double-transfer carbon printing; Artigue printing.

## Our Editorial Table.

### "PRIMUS" PHOTOGRAPH CANDLE SHADE FOR PHOTOGRAPHS.

W. Butcher & Son, Blackheath.

The illustration shows the essential parts of this little frame, which can be fitted to any candle. It is made for holding paper prints, which are slipped in at the back and held by turning over the projecting pieces. Platinotype prints are found to give satisfactory effects, but thin bromide

and silver prints may also be used. No previous mounting is necessary, but it is recommended that the prints should be made rather darker than usual to give the most satisfactory result with transmitted light. The Primus Candle Shade is a neat and useful little item, and many an amateur photographer will, doubtless, appreciate it for decorative purposes.

### THE STEREO-GRAPHOSCOPE.

Agents: S. GUTTERMAN & Co., 35 and 36, Aldermanbury, E.C.

By suitable adjustment of the lenses this instrument can be used at will, either as a stereoscope, or a graphoscope for viewing single photographs. A hood fits the face, and the oculars are likewise hooded, anteriorly and posteriorly, and thus all extraneous light is excluded from the eyes. The directions for using the instrument are as follows:—

"Turn both metal lens holders so the stops on them strike the stops on the wood holder. The instrument is then set for stereoscopic views. To adjust for single photographs reverse both lens-holders until they

strike the stops, then remove the sliding picture bar entirely from the instrument, and hold the picture in the hand. Move up or down, toward or away from you to get the proper focus."

The instrument, which, as can be seen from the illustration, is on the well-known Holmes pattern, is beautifully made and finished, and the fittings are either in brass or nickel. It should be found exceedingly useful for the double purpose, but especially for binocular purposes. It is made in a variety of woods and styles.

MESSRS. GUTTERMAN have also submitted to us a number of samples of Texoderm. This is a substance designed for the manufacture of camera case covers. It is claimed to be waterproof, and stronger than leather. It is also said to be a better imitation of any leather yet produced, as the graining is an exact representation of the original leather, and, when mounted on the camera, cannot be told from the real article, either in smell, touch, or appearance. Texoderm seems admirably adapted for its special purpose.

## THE PROCESS YEAR BOOK FOR 1899.

Edited by W. GAMBLE. 108 pp., with numerous illustrations.

London: Penrose & Co., 8, Upper Baker-street, W.

FULL as usual from cover to cover with an amazing variety of photo-mechanical illustrations and articles appealing to the process man, this sumptuous annual once more makes a welcome appearance. When we say that there are eighty illustrations in monochrome and colour, most of them full-page, and nearly forty articles by competent writers, an idea will be gained of the scope of the book. Mr. Gamble is to be congratulated on this his latest volume. It puts before us, by the aid of its many superb pictures, a key to the present position of photo-mechanical work amongst reproduction processes, and, on that account, as well as for the valuable practical information it gives, it is certain to be highly valued by all those interested in process work. Needless to say that the "get-up" of *The Process Year Book* is faultless. Aside of its technical interest, and regarded solely as a production of the printer's press, it would make a most charming gift-book to any one interested in photographic pictures.

## THE "PRIMUS" LANTERNIST'S POCKET-BOOK.

W. Butcher & Son, Blackheath.

A COPY of this little pocket-book, which contains diary spaces and much information likely to be serviceable to lanternists, has been sent to us. Ten thousand copies of the book are distributed each season free of charge. Messrs. Butcher will forward a copy to any applicant on receipt of twopence to cover cost of postage.

## CATALOGUES RECEIVED.

Erdmann & Schanz, 116, Bedford-hill, Balham, S.W.

MESSRS. ERDMANN & SCHANZ's catalogue of fine-art photographs, which occupies forty-eight closely printed pages, has been drawn up for the reference of collectors, artists, and designers. Herein we find listed reproductions of mythological and classical subjects chosen from the world's principal art galleries; flower and fruit subjects; art studies from nature; Eastern types; Paris Salon pictures; German art; English art; Italian art; British gallery work; statuary subjects; secular subjects—in fact a unique series of world-famous pictures, reproduced in various photographic processes. The catalogue should be in the hands of all art-lovers.

## News and Notes.

MR. J. J. ELLIOTT, of Messrs. Elliott & Son, Barnet, shortly leaves England on a visit to the United States.

PHOTOGRAPHIC CLUB.—September 27, at eight o'clock. Demonstration of "The Wellington Film," by Mr. Harry Wade.

MR. J. C. HOSIER, of the County Studio, Bridgewater, has erected a first-class and well-appointed studio at Wellington, Somersetshire.

MESSRS. E. SANGER SHEPHERD & CO., have recently commenced business as scientific-instrument makers at 5, 5, and 6, Gray's Inn-passage, Red Lion-street, Holborn, W.C.

A CORRESPONDENT writes: "I was pleased to read your observations this week on the R. P. S., as some of our 'artistic' friends seem to think the universe was made for them."

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, September 26, at 5A, Pall Mall East, at eight o'clock. The apparatus on view at the Exhibition will be described by the exhibitors.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. Henry Underhill, 20, Bardwell-road, Oxford, for his negative, *Children Skipping*.

AN amateur photographic society has just been formed in Harpenden, known as The Harpenden Amateur Photographic Society. The Hon. Secretary and Treasurer is Mr. Albert C. Salisbury, Limerick Hall, Harpenden, Herts.

THE session of the Photographic Class at the Aldenham Institute, Golden-crescent, Pancras-road, N.W., opens on Thursday, September 28, 1899. The teacher is Mr. Edmund A. Robias. Fees for complete course: Members of the Institute, 3s. 6d.; non-members, 5s.; apprentices under nineteen years of age, 2s. 6d. None but those engaged in the trade are eligible to attend these classes.

ACCORDING to Professor Trowbridge, of Columbia University, United States, a number of common things become phosphorescent at the low temperature of liquid air. Gum arabic appears a blue, ivory a bluish or greenish-white, cotton-wool a bluish-green, starch and paper a yellowish-green, white glue and celluloid a greenish-yellow, and kid glove a green. All these substances were put into filtered liquid air, exposed to an arc light, and examined in the dark. They continued bright for half a minute at least when kept at a low temperature after their excitation. Calcium tungstate, which is white in Röntgen rays, appeared green when submitted to the above treatment.

THE STEREOSCOPIC SOCIETY.—Owing to the death of a member, there is a vacancy in this Society, and any lady or gentleman wishing to join should apply to the Secretary for copy of rules, &c. The entrance fee is 1s. 6d., and the annual subscription is 2s. Since the Society was founded in 1893, it has circulated 1397 and divided 1360 stereograms amongst its members. Mr. Diveri, Huntly, Scotland, the Secretary, will be glad to entertain applications.

ACCORDING to the *Papier Zeitung*, where it is desired to avoid black specks in paper made in the smoke-laden atmosphere of a manufacturing district, the only effective remedy is the filtration of the air through a woven fabric of fine texture. At Schering's works, in Berlin, where photographic sensitised paper and plates are made, a circulation of air is maintained by drawing in air through cloth filters and expelling the same through powerful ventilators in the roof.

WARWICK MONTHLY COMPETITION.—The following is the list of awards of the Warwick Monthly Competition for August:—104. prize, Mr. W. H. Grimsdale, Ferry House, Twickenham, *Cows in Stream*; 51. prize, Mr. C. S. Tyler, High-street, Earls Colne, Essex, *Resting*; 11. prizes, Mr. E. R. Bull, 1, Bovill-terrace, Forest Hill, S.E., *Begging for Sugar*; Mr. H. J. Blane, 3, Cobourg-road, London, S.E., *The Road through the Woods*; Mr. B. Blaxland, 2, Willesden-park Houses, Willesden Green, N.W., *A Good Scrub*; Mrs. Cordiner, care of Mr. F. W. Cordiner, Cortes, Lomay, N.B., *A Model*; Mr. H. E. Davis, Camera Club, Charing Cross, W.C., *The Mill Bridge*; Miss Donaldson, 80, Wellesley-road, Croydon, *Evensong*; Mrs. Dickinson, 1, Milverton-terrace, Leamington, *Mixed Pickles*; Mrs. Gus Edwards, Allan House, Hereford, *An Anxious Moment*; Mr. F. W. Fielder, photographer, Foxenden, Dene-road, Guildford, *Child and Dog at Window*; Miss Hattersley, 391, Dickinson-road, Longsight, Manchester, *Winnie*; Mr. E. Hunt, Manley-road, Alexandra Park, Manchester, *Snap-shot at Woodhead*; Mr. J. G. Lawrence, 118, Petre-street, Sheffield, *Blackberrying*; Mr. J. D. Murray, Quarry-wood, Ore, Hastings, *The Seaweed Cart*; Mr. J. W. Oakley, photographer, Park Studio, Eastleigh, Hants, *The Little Man* (passenger on s.s. *California*); Mr. S. A. Pitcher, College Court, Gloucester, *North Triforium, Gloucester*; Mr. J. Palmer, 83, Upper Leeson-street, Belfast, *Carriek-a-ride Rope Bridge*; Mr. R. Perdue, P.O. Illican, Ireland, *Woman of Eighty-four Spinning Wool*; Mr. J. C. Warburg, 117, Gloucester-terrace, W., *The Edge of the Pond*; Mr. J. M. Whitehead, photographer, the Studio, Alva, N.B., *La Poupée*; Mr. E. C. Wyrall, Aldershot, *Wayside Gossip*.

THE Committee appointed by the American Chemical Society to consider the means by which the Society could hasten the adoption of uniform systems of graduation, definite limits of accuracy, and standard methods for using all forms of measuring instruments employed in chemical laboratories, have made the following recommendations:—1. That the American Chemical Society, in a manner consistent with its constitution and by-laws, ask the U.S. Office of Weights and Measures to adopt regulations for the verification of volumetric apparatus which shall be similar in purpose and scope to the regulations of the Kaiserliche Normal-Messungs-Kommission, after due consideration of the criticisms to which the latter have been subjected. 2. That the U.S. Office of Weights and Measures be asked to give special consideration to the question of a standard temperature or temperatures to be adopted for the graduation of volumetric apparatus, and to obtain, as far as practicable, an expression of opinion from American chemists on this point. 3. That the U.S. Office of Weights and Measures be asked to submit its regulations to the American Chemical Society, or a duly appointed committee thereof, for suggestions before final adoption by that Office. 4. That the international kilogramme be adopted as the standard mass. 5. That the litre as defined by the International Committee on Weights and Measures be adopted: viz., the volume of the mass of a kilogramme of pure water at the temperature of maximum density, and under a pressure of 760 mm. of mercury. 6. That all density determinations be referred to water at its maximum density and under a pressure of 760 mm. of mercury. 7. That all temperatures be expressed in terms of the hydrogen thermometer of the International Bureau of Weights and Measures. 8. That, if any question arise as to the interpretation of the above definitions, the decision and standards of the U.S. Office of Standard Weights and Measures shall be accepted by the Society as final.

## Patent News.

THE following applications for Patents were made between September 4 and September 9, 1899:—

PRINT-TRIMMING.—No. 17,792. "Improvements in and connected with a Revolving Print-trimming Apparatus, which may also be used as a Revolving Platform for Vignetting, Developing, and Toning Purposes, and for Window and Show-room Display Purposes; Box for Holding Prints, Paper, or other Articles, and a Retouching Desk." C. S. SOUTHIN.

DISHES.—No. 17,852. "Improvements in Dishes for Development and the like." P. V. LEVI.

PHOTO-REPRODUCTION.—No. 17,918. "Improvements relating to the Art of Photo-reproduction." J. T. BENTLEY.

KINETOSCOPE, &c.—No. 17,965. "A Combined Kinetoscope and Stereopticon." A. C. ROEUCK and F. McMILLAN.

CINEMATOGRAPH.—No. 17,995. "Improvements in Cinematograph Apparatus." J. MCCHEANE.

STANDARDISING ORTHOCHROMATIC PLATES.—No. 18,172. "Improved Means for Standardising Orthochromatic Plates and Testing Light Filters." J. W. T. CADETT.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

September.	Name of Society.	Subject.
26.....	Birmingham Photo. Society	Exhibition of Negatives illustrating various Brands of Plates, produced by different Developers and Methods of Working.
26.....	Hackney .....	Exhibition of August Excursion Prints.
26.....	Leeds Photo. Society .....	The Camera and the Wheel. F. O. Bynoe.
26.....	Royal Photographic Society	The Apparatus on view at the Exhibition will be described by the Exhibitors.
27.....	Kingston-on-Thames .....	Excursion: Greenwich to London. Leader, J. F. East.
27.....	Photographic Club .....	Demonstration of the Wellington Film. Harry Wade.
27.....	West Surrey .....	Annual Meeting.
28.....	London and Provincial .....	Demonstration of the Tella Camera.
30.....	Hackney .....	Excursion: Whipps Cross. Leader, F. W. Gosling.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 14.—Mr. H. C. Rapson in the chair.

Mr. J. P. Mayall passed round a collection of photographs made by the developed printing-out paper process. Since January last, when he first showed results by his method of working, he had been proceeding with the process, and had succeeded, he thought, very well. The paper, in the present case, was Trapp's mauve printing-out paper, and the negatives, in some cases, by Bulbeck & Co.

The SECRETARY asked whether there was anything special about the glazing of the prints, which showed an extremely glossy surface.

Mr. MAYALL replied that they were only equegeed on to glass. Continuing, he thought there was a quality about the developed image that could not be attained by any printing-out method, and he hoped very soon to show the truth of this by comparing some direct prints with others by development. He had observed that this Association had from the first recognised the superiority of the developed image; but, as a rule, it appeared that prints so produced had always been offered with a kind of apology because they were by development. His own view was contrary to this, and the excellence of his prints, he maintained, was due to their being developed.

Mr. PHILIP EVERITT said the Germans were amongst the first to advocate the development of printing-out paper. Two years ago he paid Dr. Liesegang a visit at Düsseldorf, and was shown round the factory. At the time some prints of limelight apparatus and lanterns were being turned out for illustrative purposes, and he secured a couple, which he passed round. Dr. Liesegang had recommended various systems of development for different tones.

An exhibition of Convention slides by various contributors then followed. Mr. Dunmore, of the Tella Camera Company, showed a series by this instrument, all being taken at f/5, the largest aperture of the Cooke lens. There-with Gloucester, Tewkesbury, Tintern Abbey, &c. were represented amongst others of a miscellaneous character. Mr. Wilfred Emery showed some views, several of which attracted attention on account of their tones obtained by uranium. Mr. H. C. Rapson had some scenes in and around Gloucester, which were very well received. Some were gold-toned and others, which were cold in colour, were sulphur-toned. Mr. and Mrs. Welford lent some work, the latter some portrait studies, and Mr. Godfrey Bingley, of Leeds, very kindly sent up a score or so, including, beside the places named, Berkeley Castle, Frampton Court, Chepstow, &c. Most of his were of a pleasing, warm colour.

### PHOTOGRAPHIC CLUB.

SEPTEMBER 13.—Mr. R. Child Bayley in the chair.

Mr. E. W. FOXLEE said it would be remembered that, when two or three months ago he showed some photographs by Mr. Witcomb, of Buenos Ayres, a question arose as to the method adopted in producing one of them, in which the same figure appeared in five different positions. In the mean time he had written to Mr. Witcomb, who replied that the group in question was obtained by placing the figure in front of two mirrors placed at an angle of 45°. He sent a sketch showing the arrangement of the studio for this work. The photograph was made for purposes of advertisement, the subject being the Argentine Minister to Berlin. The mirrors were about seven feet six inches by five feet each, and some large screens, to cut off reflections of objects in the room, were also required.

The photograph, and some others on similar lines, were declared cleverly done.

### MANCHESTER PHOTOGRAPHIC SOCIETY.

SEPTEMBER 14.—Mr. F. Edwards in the chair.

Mr. HARRY WADE read a paper and gave a practical demonstration on the NEW WELLINGTON FILM

manufactured by Messrs. Wellington & Ward. The film, he intimated, is a departure from anything of its kind in photography, and will supersede the heavy and brittle glass plates of to-day. Unlike the present celluloid films, which are inflammable and difficult to develop, besides having the faults inseparable from having a celluloid basis, the Wellington film is made of the purest gelatine only, being supported during exposure and development upon a paper backing, which, after the usual manipulations of fixing and washing, is stripped away, and the resulting negative can then be printed from either side, thus conferring a great boon to the carbon or collotype worker, who need not now resort to the process of reversing his negatives. Mr. Wade then pro-

ceeded to develop a landscape negative, which showed beautiful gradation, and afterwards stripped several negatives, showing how simple this part of the process is.

Mr. H. M. WHITEFIELD, in a few remarks at the close of the demonstration, said that the new film had evidently a great future before it, as the results shown even rivalled glass negatives, and there was also an entire absence of halation.

Mr. WADE, on behalf of Messrs. Wellington & Ward, suitably responded to the vote of thanks, saying, in response to several questions, that the speed of the films was that of any good plate of extra-rapid emulsion, and that, unlike the celluloid film, it has excellent keeping qualities.

**Hackney Photographic Society.**—September 12, Mr. E. Puttock presiding. —In the course of the evening Mr. SMITH, of the Platinotype Company, gave a demonstration of

### THE PLATINOTYPE PROCESS,

in which he developed a number of prints on all varieties of the paper, and answered a number of questions, which were put by those present. Among many useful hints given were the following: The best method of developing the cold-bath paper was to float the same for thirty seconds on the surface of the developing solution. It was better to do this than to immerse the paper wholly, as it gave more brilliant results. The paper might also be developed by brushing the developer, diluted with glycerine, over the print, and this was perhaps the best method for large prints, as it allowed more control and economised the developer. Developing with glycerine, as also with plain diluted developer, tended to produce a warmer black than when developer of normal strength was used. The demonstrator did not advise the use of a saturated solution of oxalate, as it was liable to block the shadows. The use of flat negatives was not desirable, but these might sometimes be improved by using a weak developer, or by printing under blue glass. Hard negatives could sometimes be improved by printing under green glass, and very hard negatives under yellow glass. All brands of paper required printing to the same depth, although, on the rough-surfaced papers, the image might not show so plainly by reason of the surface roughness; still, in any case, the actinometer time would be the same. The sepia paper required to be developed with the hot bath at a temperature of from 140° to 170°, otherwise the treatment was practically the same as that required for the black deposit papers. It was very necessary, however, to guard against dampness, and it was rather more easy to over-print. The paper was also more sensitive to stray light, and must not be exposed to daylight until the prints had been placed in the fixing bath. Mealy prints on platinotype paper might be caused by the paper becoming damp before printing, the use of an inferior oxalate of potash, or the cold bath being below 60°.

**Redhill and District Camera Club.**—September 12.—Mr. WILLIAM ROWLINSON, of the *Survey Mirror*, gave a "chat" on

### PHOTOGRAPHS FOR THE PRESS.

Mr. Rowlinson said that he was frequently asked by amateur photographers, why photographs they had sent to magazines and newspapers did not always reproduce as well as they expected. The reason was not far to seek, as the photographs were generally platinotypes; and this process, by reason of its matt surface, did not always lend itself to reproduction in half-tone. Photographs intended for the Press should, to reproduce well, be from plucky negatives with plenty of contrast. Mr. Rowlinson then described the genesis of a magazine illustration, from the original sketch or photograph sent in by the contributor to the finished block. He then showed the "first proof," and described how faults in the picture, due to uneven pressure on the block, were remedied. Mr. Rowlinson illustrated his remarks with a large and most interesting series of pictures and blocks.

### 1899. FORTHCOMING EXHIBITIONS.

Sept. 22-Nov. 4 .....	Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
" 25-Nov. 11.....	Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.
October 11 .....	Ludlow Photographic Society. Hon. Secretary, 14, Mill-street, Ludlow.
" 18-24 .....	Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.
" 22-Nov. 19...	Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
Nov. 27-Dec. 18 .....	American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
December 7-9 .....	Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.
" 11-Jan. 1900 .....	Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.
" 27-30 .....	Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### AMMONIA NITRATE OF SILVER.

To the Editors.

GENTLEMEN,—Your article on page 580 of your last issue, on "Ammonia Nitrate of Silver" recalls to me the fact that many chemists and silverers are not aware that a solution of ammonia nitrate of silver may be mixed with a solution of pure nitrate of silver without producing a precipitate of silver oxide, and this is the method I used to adopt to regulate the speed of emulsions. At one of the early Photographic Club meetings I mentioned this. I was immediately sat upon by several members (who shall be nameless), and whose chemical knowledge should not have induced them to exclaim "that it could not be done, and, if I did it, it would be chemical leger-de-main, and they would not believe it if they saw it." No free ammonia must be present in the ammonia nitrate solution. The easiest way to test this experiment is not to convert all the silver oxide, and after filtration mix the second portion. All the materials being pure, no second precipitate will ensue.

I need scarcely add I convinced the sceptics of their ignorance. I quite agree that paper sensitised with ammonia nitrate of silver does not keep so well as when sensitised in a plain solution of silver. Another thing, I have never been able to sensitise albumen paper on an ammonia nitrate silver. Coagulation does not take place rapidly enough to admit of the albumen remaining on the paper. True, it could be floated on plain silver first and subsequently on ammonia nitrate or on coagulated albumen. It may be remembered that I always advocated fuming the paper, and I have not changed my opinion. I remember a curious effect produced by using a small quantity of nitrate of uranium in the sensitising bath. In fuming the paper it got yellowish, but, after a day or two, it recovered its colour. I reiterate this that it may give a broad hint to plate-makers and paper-sensitisers. I believe uranium to have some wonderful photographic properties. A translation of "MM. Berthelot and Delépine's Investigations on Ammoniacal Salts of Silver" in your columns might interest your readers; at all events it will—Yours, &c., A. L. HENDERSON.

### VELOX AND KACHIN DEMONSTRATIONS.

To the Editors.

GENTLEMEN,—May we ask you to draw the attention of secretaries of photographic societies to the fact that we have made arrangements for giving demonstrations of Velox paper and Kachin developers, in all parts of the United Kingdom. Mr. W. J. Belton will be responsible for the North of England, Scotland, and Ireland; Mr. H. G. W. Claringbull, for the Midlands; and Mr. Donald A. Nightingale for London and the South Coast. Communications should be addressed to us at 20-26, Sardinia-street, Lincoln's Inn-fields, and, in order to prevent disappointment, must reach us some time during the present month. Thanking you in advance for making this announcement,—We are, yours, &c., JOHN J. GRIFFIN & SONS, Ltd.

20-26, Sardinia-st., Lincoln's Inn-fields, London, W.C., Sept. 19, 1899.

### PINHOLE CAMERAS.

To the Editors.

GENTLEMEN,—A good deal of attention is being given to the subject of pinhole photography just now. *Pearson's Magazine* recently published an interesting article on the subject. Would it not be worth the while of some of the manufacturers to put a good-class pinhole camera on the market? Such an instrument would be more than a toy.—I am, yours, &c., J. A. REID.

Kingcraig, Cutcliffe-grove, Bedford, September 19, 1899.

### THE METHODS OF OPTICIANS.

To the Editors.

GENTLEMEN,—I am very much obliged to Mr. Everitt for correcting the slips and misprints in the paper on Steinheil Lenses.

I should like to ask Mr. Everitt, who is so much better acquainted with the method of calculation actually pursued by opticians than I am

whether Sir W. B. Hamilton's work on the characteristic functions has had any very important influence on these methods? I may say that Hamilton's work (which included both optical and dynamical system, and was developed afterwards by Jacobi in his researches on differential equations) appeared before (1828-1836) Gauss's *Dioptrische Untersuchungen*. My own interest in such matters is chiefly mathematical, and, I am sure, of general interest if Mr. Everitt, or some other equally competent person, would give an account of the actual methods followed by opticians. It would be of great value as showing the special developments of the general theory, and also it might point out defects which could be remedied by study of the general theory (though I may be wrong in assuming that any optician fails to make himself perfectly acquainted with the general theory, where by perfectly acquainted I mean acquainted by study of the original).—I am, yours, &c., PHILIP E. B. JOURDAIN.

63, Chesterton-road, Cambridge, September 16, 1899.

### KODAK, LIMITED.

To the Editors.

GENTLEMEN,—I have to inform you that the Directors have declared an interim dividend on the Company's preference issue for the quarter ending September 30, 1899, at the rate of six per cent. per annum, and on the ordinary shares at the rate of ten per cent. per annum for the same period, which dividends will be payable on and after the 1st proximo.

They have further resolved that the transfer books be closed from the 20th to the 30th inst., both days inclusive.—I am, yours, &c.,

T. HALLET FRY, Assistant Secretary.

43, Clerkenwell-road London, E.C., September 19, 1899.

### AUROBA LANTERN-SLIDE CLUB.

To the Editors.

GENTLEMEN,—There will shortly be a few vacancies in the above Club, which is about to enter on its fourth year of existence, and I invite applications from good workers who would like to join us. The object of the Club is mutual help, criticism, and exchange of slides, and I think results have already proved its practical value. Being a Postal Club, the number of members is necessarily limited, and therefore I ask for early application, so that the list may be complete before arrangements for next round are made. Rules and full particulars from yours, &c.,

(REV.) F. PARTRIDGE, Hon. Sec.

St. Clothar Vicarage, Egloskerry, R.S.O., Cornwall.

### THE TANQUEREY PICTURES.

To the Editors.

GENTLEMEN,—Our delightful parish of Hawkhurst is now being favoured with a batch of circulars from Mons. Tanquerey, couched in the usual flattering terms, and accompanied by a list of testimonials and a special coupon. One of these offers was sent to me at my private address, and I had some thought of sending my portrait just to see what would happen, but this morning I have seen a sample of the work going through to the lady at the rectory of the next parish, and, under the circumstances, have decided not to make the experiment. This specimen is a roughly mounted bromide enlargement, about 15 x 12, finished by the air brush and a few strokes of a hair brush, presenting a soft, pleasing appearance, the little work done on the print being effective, and producing a soft, woolly, stippled effect, no doubt pleasingly flattering. The value of the work would be about 7s., and so as good as one could expect as a gift, but the one thing about it which deters me from trying my fortune is that the carriage of this precious work of art is no less than 6s. 3d. This will be slightly augmented by the time the carrier has delivered it, making a total of at least 6s. 6d. to pay for carriage. If this is the way the rector's lady is served, I wonder how less illustrious individuals are.—I am, yours, &c., E. WILLIAMS.

Highgate, Hawkhurst, September 18, 1899.

### CLOUDS.

To the Editors.

GENTLEMEN,—There is a printer's error in my letter on "clouds" which renders the meaning rather obscure. In the last line but one it reads thus: "With an ordinary plate shutter," which should be, "with an ordinary flap shutter," the difference being obvious.—I am, yours, &c., COLONEL.

Newport, September 16, 1899.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

- A. Freke, 12, Duke-street, Cardiff.—Photograph of Park Hotel building, Cardiff.  
A. A. Cooke, 78, Somerset-road, High Cross, Tottenham, N.—Photograph of A. A. Cooke.

J. C.—We have written the firm. So far as we know, they are respectable.

REVERSED NEGATIVE.—W. PAGE. The reversal of the image, as regards right and left, is easily accounted for. The plate was put into the slide wrong side foremost.

IODISERS.—A. W. says: "Will you kindly give a few formulae for iodisers to adding to collodion when required for sale?"—Several formulae are given on pp. 1055-6 of the ALMANAC, all of which are good.

FOGGED BROMIDES.—SOUTH WALES asks the cause of the want of brilliancy and lack of whites in some contact bromide prints he sends.—The cause is that the paper is "light struck," that is, it has been exposed to light at some time or other.

LIGHTING SITTER.—S. COHEN. The portraits are by no means good. The fault in them is that they are lighted with an almost direct front light, which causes them to be flat and map-like. Stop off all direct front light, and illuminate the sitters by a front side light. There is also far too much top light.

PARAFFIN LIGHT IN STUDIO.—IMPRECUNIOUS asks "if it is possible to take good portraits at night by the light of six or eight good paraffin lamps?"—No, it would be impracticable. If you want to take portraits by artificial light, why not employ magnesium as a flashlight? It would not come expensive, and is very effective when rightly used.

EFFECT OF CARBON WORK ON THE HANDS.—R. W. writes: "Would you let me know if carbon work has been known to affect the hands, and, if so, what are the symptoms?"—Yes, but only after long and continual use. The first symptoms are a violent itching on, or between, the fingers, accompanied by minute watery pustules. These are the general symptoms.

STAMP PORTRAITS.—B. B. B. asks: "Can you tell me of any house that keeps the necessary appliances in stock for taking stamp portraits and perforating them. I am told that they are only made to order, and are not stocked by any one?"—They are stocked by most of the large houses, such as Maron's, Fallowfield's, and the like. If we mistake not, the latter named make rather a speciality of them.

BLACK SPOTTING MEDIUM, &c.—BLACKING says: "1. Can you tell me where I can get, or how I can make, a good jet-black, matt-spottling medium for finishing Velox prints and platinotypes? 2. Also the best thing to use for sticking P.O.P. prints in an album without buckling the leaves?—Ordinary water colours, say ivory black and indigo, to match the colour of the prints. 2. The best mountant for the purpose is a solution of gelatine containing a large proportion of alcohol. A formula for a mountant specially for the purpose is given on page 1061 of the ALMANAC.

RED LIGHT AND THE EYES.—OPERATOR says: "After I have been at work in the dark room, which is lit with a dark ruby light, for half an hour or so, and come into the studio, my eyes pain me very much. The strong light almost blinds me for a time, and my eyes pain me very much. Can you suggest any remedy, as I am afraid it may injure my sight?"—We should advise you to put on a pair of dark spectacles, known as "London smoke," before leaving the dark room. Possibly you are using an unnecessarily obscure light. Try deep orange in place of the ruby glass, and do not work too close to it.

PLATINUM TONING, &c.—T. KING says: "1. Will you kindly give me a good formula for platinum toning bath for gelatine chloride paper? please give it in a bath that will tone a sheet 24½ x 17 perfectly. 2. Would a Dallmeyer group and portrait lens give as good portraits as a Ross portrait lens? I want to use one if possible for the two purposes. 3. Will you please give me your candid opinion of the enclosed photograph?"—Chloro-platinite of potassium 10 grains; water, 20 ounces; nitric acid, 3 to 8 drops. 2. Yes, quite as well, but it will be slower in action. 3. The photograph is a very good one.

MIDGET PHOTOGRAPHS.—H. R. F. says: "1. I shall feel greatly obliged if you can inform me where I can get the material (sensitised cardboard or thick paper) for producing midget plates on as enclosed. 2. How is the name put on? it seems to me to be printed through a film placed in front of negative. 3. Who is the maker of frames for printing a dozen small bromides on one piece of paper from one negative?"—1. The print seems to be on ordinary bromide paper and mounted on the card, the margins of the negative being masked. 2. The name was probably on a thin film interposed between the negative and the paper. 3. Messrs. Seaman & Sons, Chesterfield.

RED IODIDE OF MERCURY.—T. S. M. W. says: "Will you kindly give the formula for making the red iodide of mercury of Mr. Watmough Webster, referred to in your article on 'Reduction and Intensification in Professional Work?'—Simply add a solution of iodide of potassium to one of bichloride of mercury, and the red iodide will precipitate. An excess of the iodide must be avoided or the precipitate will be redissolved.

SAL D'OR TONING BATH.—W. G. ORME. You could not have accurately followed instructions, but it is difficult to say where the error comes in. No precipitate of a reddish colour is formed in making sal d'or. Any such precipitate consists of reduced gold, and may result from (1) impure water; (2), dirty vessels; or (3), most probably pouring hypo solution into gold instead of vice versa. Excess of soda might be a contributory cause. Sal d'or is a colourless deliquescent salt.

MISTAKE IN MOUNTS.—PROVINCIAL says: "I ordered, through a small dealer here, who said he would get them from Germany, some mounts. Now that they are delivered, I find my name is wrongly spelt. The dealer declines all responsibility, and refers me to the firm in Germany from whom he ordered them, giving me their name. Who is responsible?"—The dealer from whom you ordered them. He must settle the matter with the manufacturers. Simply return the mounts to him, and refuse to pay for them.

BACKGROUNDS.—R. TROPFEN writes: "I want to make some sketchy backgrounds for vignettes and bust portraits. Can you tell me if sheets of white and brown paper are to be had as large as about five feet by four feet? If so, where they can be purchased?"—Yes. White and also brown paper can be had of any length, and of about five feet wide. The former is sold by artists' colourmen under the names of cartridge paper and cartoon paper. The brown is sold by upholsterers and large stationers under the name of carpet paper.

FACTORY ACT.—G. & R. ask: "We employ six persons (women) where we do our printing and mounting. An inspector has been to us and tells us we come under the Factories Act, and we must conform to its rules as regards hours of work, half-holidays, &c. Will you please say if photography does come within the Act, because it will make our work, with the shorter hours and the half-holidays, come much more costly; indeed we shall have to take on another hand, perhaps two, as the six we have now can hardly get through the work?"—Yes, your place does come under the Act, and you will have to abide by it, and, we expect, your employees will not be sorry for it.

SALARIES IN NEW YORK.—F. N. says: "Would you kindly inform me what is the usual salary paid to operators in New York City, first and second class, or a rough idea of same? And what is your opinion with regard to the qualifications necessary? Any information would greatly oblige."—In reply: We have no means of telling what salaries are paid in New York. Our correspondent's query may catch the eye of some American who can give the desired information. As to the qualifications necessary, we may, in general, say that, from what we can gather, a greater degree of smartness and ability is required by American photographers than is usually accepted by English employers.

MARKING ON FILM NEGATIVE.—E. G. R. says: "I shall be obliged if you will kindly tell me the cause of the circular yellow mark in the enclosed negative. The film is by Austin Edwards, medium speed; developer, pyro (with sulphite of soda) and carbonate of soda, with a trace of bromide of potash; fixing bath, one in five of plain hypo. The film was in the fixing bath quite a long time, say twenty or twenty-five minutes. I did not notice the mark till the film was dry after washing, of which it had an hour in running water."—The cause of the spot is imperfect fixation, through an air bubble being allowed to remain in contact with the film while in the fixing bath. You might try refixing the negative, but it is doubtful if the spot can be removed.

LANTERN SLIDES AND STEREO TRANSPARENCIES.—LANTERNIST says: "Would you please tell me: 1. How the tone of the enclosed slide may be obtained? It is a colour I admire, but I have never been able to produce the shade. 2. What film supplies a film which may be used to make stereoscopic transparencies with? 3. How might the back of a film be matted so as to do away with ground glass?"—1. The slide appears to be by the collodion process, but similar tones may be obtained on the ordinary lantern plates by a modification of the developer. Try some of the developers given on pp. 1033-1035 of the ALMANAC. With them almost any tone may be obtained. 2. Any of the films who supply films. 3. Any of the manufacturers of films will, doubtless, coat you some on celluloid with a matt surface on the reverse side. Celluloid with a matt surface is a regular article of commerce.

BLISTERS ON ALBUMEN PAPER.—A. BREXTON says: "Could you give me the reason and a cure for blisters on albumen paper? I use — & Sons' double, and take great care in all operations, &c., but get my prints absolutely covered with immense blisters, sometimes as large as a half-crown piece, besides thousands of what I call 'pimples.' I always make up the hypo hours before using, so it cannot be change in temperature of the baths. These blisters only appear in the washing water immediately after leaving the hypo. It is really the greatest trouble I get in all my work, as it is so difficult to wash prints, as they all float on account of the air enclosed?"—In reply: Some papers are more prone to blisters than others, particularly the double albumenised. The best way we know of preventing the blisters is to immerse the prints, dry in methylated spirits for a minute or two before commencing to wash out the free nitrate of silver, then proceed in the usual way. The following method will often obviate blistering. When the prints are fixed dilute the hyposulphite solution with an equal part of water and let them remain in that for a few minutes, then dilute further, before putting the pictures into the washing water.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The

formulae will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÀ.

THE correspondent of a contemporary echoes a recently expressed regret that, comparatively, so few people devote themselves to the pursuit of the knowledge that after all is surely the only subject worthy of the attention of mankind. "Politics, trade, law, letters, and the like, engross the attention of nine-tenths of us, and the recruits for science are few and far between. Is it not time something were done to alter this, and to train up the coming generations in the service of science, that the abundant promise of the last hundred years may bear fruit a hundredfold during the coming century? I feel sure," he adds, "that there are thousands of fathers who will feel as I do, and I venture therefore to ask for a little information. A middle-class man with a fairly large family of boys, most of whom have done fairly well—generally after wriggling their round selves out of the square holes into which I had fitted them—I want to know how I could start the youngest, a boy of sixteen, of average intelligence, but no

special bent, and educated at one of our second-rate public schools, in some career in which he might work for science and—earn a modest living? It is possible that some of your readers who have been through the mill may give hints. They would, I feel sure, be welcomed by many well-meaning parents. I am not pleading for facilities for the embryo giants of science. Their abilities will find recognition and encouragement, like those of Faraday and many others have done in the past. I only ask, in the first place, how it is possible to start average lads in the pursuit of some branch of scientific work which shall yield bread and cheese and the prospect of really benefiting their fellows instead of robbing them." May we suggest to this gentleman that some of the higher branches of photographic work might satisfy his laudable anxiety on behalf of his son?

\* \* \*

We join with the *Daily Chronicle* in protesting against the public exhibition, by stereoscopic and other means, of improper photographs which many persons are exploiting in some parts of the country. Throughout London and seaside towns just now, points out our contemporary, there is a craze for the exhibition of photographic reproductions of pictures by various mechanical devices. "We do not refer to exhibitions in the parks such as have come under the notice of the police, but to more pretentious penny shows open to the young, to which we would also direct the attention of the police. It has been brought to our notice that many of the pictures exhibited are suggestive, and that some are grossly indecent. The police seize 'Continental works of art' in shops where few people see them; why permit equally objectionable shows open to the multitude?" We trust the authorities will exercise every vigilance in this important matter. So far as the world of photography is concerned, there is comfort in the reflection that these degrading exhibitions do not owe their origin to legitimate photographic enterprise; but we, nevertheless, hope that photographers will be the first to discountenance this prostitution of the camera to such ignoble ends.

\* \* \*

THE Vienna correspondent of the same journal gives an interesting account of the degree of confidence which Her Majesty the Queen reposes in Professor Angeli, Her Majesty's favourite painter, who has recently been intrusted with the execution of a portrait of the Queen. It appears that for the last twenty years the Queen has had her portraits painted exclusively by Professor Angeli, a fact which has caused jealousy to many an English and foreign artist. Professor Angeli, in the course of an interview, said: "The Queen would not sit to anybody else for five minutes. To me, however, she sits for hours whenever I like. Her Majesty has got accustomed to me; to be constantly looked at by another man would greatly annoy her." While sitting to Professor Angeli, letters, telegrams, and even State documents are read to the Queen by Princess Beatrice. Professor Angeli enjoys Her Majesty's highest confidence. No secret (he says) is hidden from him. The last time the Queen was sitting to him at Windsor Castle, on the occasion of her eightieth birthday, she wished to be taken simply as a woman, not as the Queen. This portrait, at Her Majesty's desire, is to be reproduced for circulation amongst the English people. The Queen, however, will not allow the original portrait to be used for reproduction, so Professor Angeli will make a copy of it.

We do not know whether any of those photographers whom Her Majesty honours by sitting to them for her portrait possess anything like the exceptional privileges which Professor Angeli appears to enjoy; but, at any rate, we take it that their sittings frequently occupy more than five minutes, although the Professor appears to think that Her Majesty will not sit to anybody else for that length of time. At any rate, Professor Angeli may be sincerely envied for the very great favour which he alone, of all the world's artists, appears to enjoy at the hands of the Queen-Emress. Commenting on the interview, the *Chronicle* says: "What a pity that Her Majesty did not choose an English, or a Scotch, or an American artist, and get accustomed to him! Millais would not have looked at her more than was necessary, and, as a painter, he was worth a dozen Angelis. Mr. Sargeant would have been a model of discretion, and would have painted a portrait with tremendous force." Perhaps, however, Professor Angeli was not so indiscreet as the interviewer makes him appear to be.

\* \* \*

THE theatre of the Society of Arts has for years past been the scene of a great many meetings and lectures of direct interest to photographers. Such men as Abney, Warnerke, Bolas, Dallmeyer, Ives, Traill Taylor, Lippmann, Beek, and many others have figured amongst those who have addressed audiences there on subjects of the highest importance in theoretical and practical photography, and at times the Royal Photographic Society and the Camera Club have had the free use of the lecture-room for their meetings. There is no doubt that, in this and other ways—particularly by the devotion of some of the celebrated Cantor lectures to photographic subjects—the Society of Arts has rendered very material assistance to the cause of photographic progress, a work in which it has had the immediate sympathies of the Secretary of the Society, Sir Henry Trueman Wood, whose services to photography have been many and various, as our readers are aware.

\* \* \*

THESE remarks are suggested by the circumstance that, in the last number of the *Journal of the Society of Arts*, a brief history of the Society between the years 1754 and 1899 is given. We have set before us a modest estimate of the very great beneficial influence which the Society has always exercised on the arts and sciences. We learn that it is one of the three oldest of the learned and scientific societies in the country. In the department of fine arts, we are told, it had a share in assisting the education and encouraging the youthful efforts of many of the most eminent artists from the time of Reynolds to our own days. On its prize-lists are found the names of Richard Cosway, Joseph Nollekens, George Romney, Sir Thomas Lawrence, P.R.A., Sir William Ross, William Mulready, Thomas Bewick, Aloys Senefelder (the inventor of lithography), John Flaxman, W. Wyon (the medallist), Sir Edwin Landseer, Sir Charles Eastlake, P.R.A., W. P. Frith, J. C. Hook, Sir J. E. Millais, P.R.A. One of the first, if not the first, public exhibitions of pictures in London was that held in 1760 at the Society's rooms in the Strand, near Beaufort-buildings, an Exhibition which really led to the foundation of the Royal Academy in 1768.

\* \* \*

THE history continues: "The great improvement in decorative art which has marked the last half of the present century in this country may be said to have had its birth in the Society

of Arts. Chiefly owing to the strenuous efforts of the late Sir Henry Cole, the Society originated a campaign against the ugliness and ignorance in artistic matters which was certainly prevalent in England about the end of the first half of the century. Its efforts were for a long time met with ridicule, but public opinion was gradually converted, and the value of beautiful and artistic surroundings in daily life, instead of being a matter to be sneered and laughed at, is now regarded as a matter of course. Moreover, the Society took an active part in the improvement of the Patent Law, since the first improvements in 1852 down to the last Patent Act of 1883. It was the action of the Society that first secured protection for copyright in works of art. Its Food Committee was one of the earliest agencies to draw attention to the necessity of providing means by which meat and other foreign food products could be successfully imported. One of its committees for a long time urged on the Post Office the necessity for a Parcel Post (suggested in 1858), and worked up public opinion until it was granted." This little history of the Society—it was to the Society of Arts, by the way, that the idea of the 1851 Exhibition was due—should be read by all those concerned in tracing the causes that have influenced artistic and scientific progress during this century. Assuredly, as we have before remarked, photography owes not a little to the encouraging recognitions which it has so long received at the hands of the Society, Sir Henry Wood, and his predecessor in office, the late Mr. P. le Neve Foster.

\* \* \*

MESSRS. CADETT & NEALL, of Ashted, ask us to notify that they have now made arrangements that, in the future, dealers will be able to secure smaller quantities of carriage-paid goods of their manufacture than in the past, by which they anticipate they will not receive complaints of difficulty in obtaining their various brands in certain parts of the country. This concession will be to the advantage of distributor and user, inasmuch as plates and paper can now be bought in such quantities as to be a guarantee that "Cadett" brands are of the freshest manufacture.

#### PERMANENCE OF THE BROMIDE PROCESS.—II.

REVERTING to the subject of the permanence of bromide pictures—and we might add also gelatine prints generally—we shall here refer more fully than in the previous article to the means by which the changes that have taken place in pictures by this process might have been avoided. These must not, however, as is too often the case, be charged to the *carelessness* of the workers, but, rather, to the work being put into the hands of assistants who are utterly ignorant of the principles upon which either fugitiveness or stability depends. This remark not only applies to assistants but to many who are now making enlargements at a cheap rate for the trade and others. In many cases their knowledge of photography is entirely mechanical; they have no theoretical knowledge whatever of the process by which they produce their work—often good to look at, though it may contain the seeds of its decay. Under these circumstances it is not surprising that one sees so many gelatine pictures, both enlargements and direct prints, that have undergone a marked change, though not faded, within a comparatively short time. We again emphasise this matter because it has been, and is, bringing discredit on a valuable process which it does not deserve.

In the former article we alluded specially to pictures developed with the ferrous oxalate, being—indeed generally—put into the fixing bath while they still contained a considerable amount of free acid, and how that was one of the frequent causes of a speedy change. The remedy in this case is obvious—elimination of the last trace of acid before the picture is introduced into the hyposulphite solution. This is not altogether the easy matter that might be surmised. Let any one after developing, say, an enlargement, and giving it the usual amount of washing—nay, an extra amount—drain it pretty closely and then press a slip of blue litmus paper on its surface and see the result. This will show, in the majority of cases, when the ferrous-oxalate developer is used, that the pictures go into the fixing bath while they are in a decidedly acid condition, and, as a consequence, the hypo is decomposed in the gelatine film, and in the paper supporting it, setting free sulphur and sulphur compounds which may well be expected, eventually, to act mischievously.

It may be urged, by those who produce bromide enlargements at an exceedingly cheap rate, that it would not pay to so thoroughly wash each individual picture so that no acid remains when it is put into the hypo, but with that we have nothing to do, that is their business and not ours, we simply point out the conditions. There is, however, no necessity now to use the acid iron developer and the subsequent acid bath at all, as several of the new developers will answer the purpose quite as well and yield quite as good colours. They would, of course, obviate this source of uncertainty.

There is, however, another very prolific source of the discolouration of bromide pictures—and here chloride ones must also be included—namely, imperfect fixation. In the previous article (see p. 564) we alluded to the reactions that take place in the fixing bath, and pointed out the necessity of perfect fixation in order to get the hypo compounds into a perfectly soluble condition so as to be capable of elimination by washing.

Now, how are these conditions fulfilled—or rather not fulfilled—in a great majority of cases? We are now referring to chloride prints as well as bromide ones, as precisely the same state of things obtain. The formulæ generally given for the fixing bath, for both bromide and chloride pictures, is weaker than used to be employed for albumen prints, and the time of immersion also less. Hence it will be seen that gelatine pictures do not, as a rule, get the same degree of fixation that those by the older process did; whereas, with the thicker film, they ought to have more rather than less. Furthermore, far more pictures are generally fixed in a given quantity of solution than used to be the case with albumen prints, and, as a consequence, the hypo-silver compounds are not got into the necessary soluble state to ensure their complete removal in the after-washing, however prolonged that may be. In some instances prints still contain salts that are sensitive to light, as witness the actual darkening of many pictures by a prolonged exposure to light.

We recently saw in a London suburb, where photographs of local scenery are sold, a dozen or two of prints on gelatino-chloride paper, framed and hanging outside a shop, that were in a woful plight. In some the skies and lights had become of a deep yellow colour, in others they had become a purple brown, and the prints much darker generally than they were at first, and many of the pictures clearly showed that light-sensitive salts were still in the film and in the paper, *i.e.*, the action of the hypo had not been complete. No amount of

washing, had the prints been subjected to it, would, in such a case as this, have prevented the discolouration with long exposure to light.

As we have said before, with perfect fixation a comparatively short washing will suffice, but without that no amount of washing will confer stability. Therefore hypo should be lavishly used (and it is cheap enough now) and plenty of time given for its action; and as an extra precaution the prints, after being fixed, should be immersed in a fresh solution of hypo for five or ten minutes before they are washed. This applies alike to bromide enlargements and prints on P.O.P., when the greatest stability is required.

It will probably be said by some that all this involves extra trouble and increased expense, but with that, as we have above intimated, we have nothing to do. Our object is merely to point out how the greatest degree of permanence is to be secured in gelatine pictures, and nothing more.

#### THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Forty-fourth Annual Exhibition of the Royal Photographic Society, and the last to be held in the Gallery of the Society of Painters in Water Colours, at 5A, Pall Mall East, was preceded on Saturday last by the usual Private View and *Conversazione*. At the latter function, in the evening, the place of the President (Lord Crawford) who is unfortunately suffering from severe illness (from which we are sure all our readers will wish him the speediest possible recovery) was taken by Major General Waterhouse, who with the Council received the members and guests. The unfavourable weather was, doubtless, the cause of a smaller attendance than usual; nevertheless, the gathering was large and representative, and if the time-honoured difficulty of studying the exhibits was felt quite as fully as hitherto there was the compensating consolation of ample opportunity for those pleasant little exchanges of friendly greetings; the meeting of acquaintances parted, perhaps by the span of a twelvemonth, and a comparison of notes on things in general and photographic matters in particular, which invariably and agreeably characterise R.P.S. *Conversazioni*.

It was a positive relief to escape from the interested nonsense and puerilities that were recently uttered in certain quarters anticipatory of the Exhibition, and get to an inspection of the display itself. So far as we could discover—and we are not deficient in opportunities for gauging the opinions of those most concerned—nobody whose views count for anything at all in the matter cared two straws about the momentous injustice of not permitting the Judges to co-operate in the work of selection. The fuss that has been made over this trifling affair finds its inevitable sequel in a chorus of approval of the way in which the selecting and hanging has been done. A member of the Selecting Committee remarked to us, on Saturday evening, that possibly on reconsideration some few of the photographs on the walls might have been excluded; but amongst the hundreds that were rejected in all probability there was even a smaller number that might have been included in the Exhibition. We doubt if this satisfactory state of affairs could be bettered by calling in the assistance of those heaven-born Judges who have whimpered at their exclusion from the Selecting Committee.

The dominant characteristics of the present Exhibition may be hit off in half-a-dozen lines. As we prognosticated a few weeks ago, nothing startling is on view. The lantern slides and other transparencies show a falling off in numbers and quality. Novelty is not perceptible in the Technical Section, and practically the whole of the apparatus exhibits has been before the photographic world for months past. Coming to the Pictorial Section, we discern less of the imitative mud-flat element than hitherto—a welcome revolt, by the way—and the portraiture is distinctly better and brighter than last year. In architecture, improvement is conspicuous, while in some of the figure studies there is a *verve* and decision of effect which we have not seen equalled for years past at this Exhibition. On the whole, we should say that, regarded from the strictly photographic point of view, the Exhibition is a shade the better of its immediate predecessor. The work of the lens, the camera, and the dry plate is more strongly in evidence than the efforts of the photo-faker and the misguided people who have hitherto confused nebulousity and sombreness of result with pictorial photographic effect. At Pall Mall just now,

in short, we have a collection of photographs which, with few exceptions, do not leave the spectator in doubt as to what they are meant to be, or by what methods they have been produced.

The Judges this year were Mr. Horsley Hinton, Mr. Harold Baker, Colonel Gale, Mr. W. L. Wyllie, A.B.A., and Mr. B. W. Leader, R.A. They awarded ten medals as follows:—

21. <i>Head of an Old Man</i> .....	Dudley Hoyt.
130. <i>Summer Shades</i> .....	J. H. Gash.
139. <i>The Miller's Workshop</i> .....	W. T. Greatbach.
191. <i>After Rain</i> .....	C. F. Inston.
217. <i>In Wirksworth Church</i> .....	W. R. Bland.
278. <i>Sunny Pastures</i> .....	E. G. Boon.
276. <i>Roses</i> .....	J. M. Whitehead.
299. <i>Vignette in two Colours</i> .....	A. Stieglitz.
333. <i>Absorption (copy of etching)</i> .....	J. H. Player.
388. <i>Engraved Screen Plate (200 lines to inch)</i> .....	J. E. Johnson.

All but Mr. Stieglitz and Mr. Inston take a Pall Mall medal for the first time. Already there has been some discussion over the judging, and the opinion has been very freely expressed to us that, with an alteration of the personnel of the photographic members of the jury, the destinations of at least three, if not five, of the medals would be changed. It is best to speak plainly in matters of this sort, and we say at once that there is considerable room for discontent with this year's judging.

One extraordinarily remarkable coincidence has to be noted. Last year medals went to Mr. W. J. Warren (Leeds Camera Club), Mr. C. S. Baynton (Birmingham Photographic Society), and Mr. G. E. Thompson (Liverpool); this year medals go to Mr. J. H. Gash (Leeds Camera Club), Mr. W. T. Greatbach (Birmingham Photographic Society), and Mr. C. F. Inston (Liverpool). We feel obliged to say that the coincidence is all the more noteworthy inasmuch as quite as good work as these gentlemen show comes from other, if less "pictorial," parts of Britain. Nevertheless, we heartily congratulate the medal-winners on their success, and wish them many more triumphs at Pall Mall and elsewhere.

The standard of work in the exhibition is exceedingly high—there are but few false notes among the whole number of pictorial exhibits—and there are nearly 370 of them, a fact that speaks volumes for the exhibitors' artistic progress and the Society's care of selection.

"Schools" are becoming less the fashion, and individual work once more pushes its claims to public recognition, and with evident success.

Let us look at some of the work—we cannot take it picture by picture, for space will not permit, but we will note a few of the things that struck us as being worthy of comment; and, as in our notes on the Salon, we will try and take the exhibits of the workers as their names appear in the catalogue.

First comes Mr. W. J. Croall. We are sorry to see only two examples from this talented gentleman; one appears in the catalogue as a reproduction of his picture of a sporting dog which he calls *Steady*, and the other is a glorified Convention snap-shot of some sheep under a tree with the appropriate title of *Mid-day Rest* (No. 10). The grouping of the sheep is excellent, but they have been "lost" somewhat in the process of enlargement.

No. 4, *Spring Pastoral*, the work of Mr. A. Cochrane, is a more ambitious effort and is also beautifully reproduced in the catalogue.

Every effort has been made to bring the picture together into one harmonious whole, evident pains have been taken to subdue an obtrusive light or to soften an over-heavy shadow, and the result is very beautiful; the only thing that particularly impresses itself upon us is the great contrast made by the very light sheep and the very dark background, this has the effect of making the subject look somewhat "scattered," and a wee bit of toning down in the high lights on the before-mentioned animals would be a considerable improvement, and with the light behind the trees would the sheep not cast shadows?

Nos. 5 and 152 are also the work of this gentleman, but the first is the most worthy of careful study.

Mr. Greatbach sends seven examples—all of them careful works, and several most artistically treated, notably No. 97, *A Woodland Path*, which somewhat resembles Mr. Percy Lund's picture last year. No. 122,

*The marsh is frozen,*

*The river dead,*

is very fine—almost like a silver print drawing, and his medal picture, No. 139, *The Miller's Workshop*, was a wonderful triumph of both artistic and technical skill; quite free from halation, perfect in tone, a simple subject has been made worthy of the coveted award by a combination of the principles of both science and art. The slightly open door sounds the key-note of the composition—take this away and the picture

would become flat. No. 250, *The Mill Stream*, is somewhat lifeless, and is not so good, though beautifully composed. No. 279, *A Summer's Day*, is a charming little landscape, but the shadows are rather heavy.

Mr. W. J. Warren has several well-executed examples; the first, No. 7, reminds us somewhat of Mr. Hinton's picture in the Salon last year, though the treatment is altogether different and strikes us as being somewhat too heavy. No. 105, *At Concarneau*, is full of life and movement; it is a busy scene amid market boats. No. 232, *The Ambulatory Tewkesbury*, is a fine architectural bit, and No. 248, *A Sunny Glade*, particularly appeals to the admirer of detailed riverscape scenery, but *The Terrace at Haldon*, No. 137, is our favourite. Mr. Ralph R. Rawkins has a nice little landscape in No. 8, *A Dorset Meadow*, and No. 220, *Watching the Sunset*, is a picturesque little cottage scene much in the style of Peter Ghent (Liverpoolians well know this artist's work, and whose masterpiece was purchased for the permanent collection at one of their galleries).

The work of Mr. Charles Job deserves special attention. The first (No. 9) is reproduced, and is an artistic rendering of a difficult subject. The old buildings are not as picturesque as they might be, and there is a feeling, as you look at the picture, as if it had something lopped off somewhere. This is due to the tall masts of the boats being seen without the hulls, and we are not sure if the omission of the two principal masts would not improve the effect greatly. No. 67, *Repairing the Harness*, is a delicate bit of work, but we like No. 165 for vigorous treatment.

The head and figure studies this year are again excellent, and it is almost invidious to make distinctions; but Mr. Speight, Mr. Ralph Robinson, Mr. Warneke, Mr. Dudley Hoyt, and Mr. Sidney Underdown, Mr. William Gill, and Mr. Alfred Werner, are all household names, and one naturally looks for something above the average from such gentlemen, and this year we are not disappointed.

The medal given to Mr. Dudley Hoyt (An American, by the way) was supported by universal public opinion, his *Head of an Old Man* (No. 21) being the portrait of the year at the "Royal." Unfortunately, this is the only exhibit from our American cousin. Mr. Ralph Robinson fulfils all that is expected of him, which is saying a great deal. Mr. Warneke's work was also much admired, but Mr. Harold Baker did not send much this year for us to admire, and he seems rather bitten by the architectural craze. There are others whose work we may have occasion to note as we proceed round the gallery.

Mr. Page Croft, versatile as ever, sends in nine exhibits varying from portraiture to landscape, *An Idle Apprentice* (No. 26), a portrait of *Herman Vezin, Esq.* (No. 27), *The Toilet* (No. 49), obviously inspired by Etty. *On Guard* (No. 63) *December* (No. 175)—This is more a "Salon" subject, brown, and sombre, and subdued, like Nos. 231 and 278.

There is a lot of feeling and sentiment in Mr. R. S. Webster's picture of *Sir G. Reid* (No. 33), and No. 40 by Mr. A. Knyvet Gordon might be entitled *My Mother made me Braid my Hair*. Mr. William Balston's *Effie* is a bit of rare technical work, and Mr. F. H. Evans's portrait of *Mr. Storey* (No. 55) is also good. Mr. Ernest G. Boon sends many exhibits (13). No. 240, *Alasians Beaching a Boat*; and No. 310, *Shipping, Genoa*, struck us as being particularly good work. His medal picture, *Sunny Pastures* (No. 273), was the subject of much comment, the more advanced section praising it and the moderatists denouncing the award; and, whilst admiring the work, we cannot say it appeals to our inner sentiments like some others that we could mention.

Mr. Francis A. Bolton sends three pictures. No. 58 is a headland, with clouds and nice foreground, but wanting in interest; No. 117 is rather a misty tree study, and No. 229, *November in the Woods*, requires no description.

Dr. Llewellyn Morgan's exhibits are mostly inspired, we should surmise, by the beauties of his native country, with the exception of his *Font at York Minster* (No. 168), which is a fine bit of work. His *Falls in Sunshine* (No. 178) is the most artistic treatment of a waterfall we have ever seen. Usually waterfalls are ugly, and white, and stiff, but here the doctor has interposed foliage and rocks, and so manipulated his light and shade as to give us a beautiful picture. His other cottage subjects are very Welsh, and are startlingly like some of the studies of the artist we referred to before (Peter Ghent) at his best.

There are one or two pictures of the Paul Martin night school. No. 60 is one of them, but the chief exponent is Mr. W. A. Fraser, and six pounds seems a lot of money for No. 142, except it were paid by the proprietors of the paper whose circulation is announced in letters of fire, the eyecore of the picture. They are, no doubt, all very clever, particularly the one (No. 206) entitled *A Winter's Night*, where the mystic light falls on the snow mounds, giving the scene a weird effect. Yet we would like to see Mr. Fraser turn his talent in other directions.

Now we notice the picture by Mr. Alexander Keighley (No. 60). The tone of rich sepia suits the subject well, the sky is simply perfection, and the value of it enhanced by the deep tones of the landscape beneath. The composition is somewhat diagonal—a long and almost unbroken road leads to a distant mill; all this is in deep shadow, and the sky benefits thereby. No. 155, *Cow Parsnips*, is another but entirely different piece of work, being a very excellent study of this pretty feathery summer weed. All the surroundings are darkened, and kept under to give value to this useful foreground study. No. 228 is Mr. Keighley's greatest effort. The title, *My Lady's Garden*, raises our hopes. We associate it with all that is sweet, and dreamy, and lovely in form and colour, and we have no doubt Mr. Keighley's poetic temperament fired his ambition to emulate the glories of Marcus Stone, and surpass him in photographic excellence. The effort is great, but we should like to ask Mr. Keighley what has scratched the peacock's back, and what those sunflowers have done to grow such strange marks on their flowers and stems, and who cracked and tried to mend the stonework?

For those who will not see this picture, we will try and describe it.

It is an old garden, with lofty trees towering high above the gravel walks on the left, and beneath their shadow an ancient sun-dial covered with lichens, the signs of age and decay, and near by a peacock, which gazes across the path with glowing admiration at my lady, who is attired in a gown of the Empire period. (Forgive us, Mr. Keighley, if we are mistaken in the period; but it looks like it, and fits the scene, as well as the wearer, to a T.)

The lady is tall and stately, and is gathering from an Old English flower-bed some of the blossoms, whilst hard by tall sunflowers rival her in height and beauty. The tall and distant hedges are relieved here and there by graceful foliage and a quaint old bit of stonework. The whole is treated in a rich brown sepia; the idea and *motif* our readers may judge for themselves, though the execution may not be all that is desired. Mr. Keighley, try again. You have got a magnificent groundwork; trust to photography, and let the pencil and brush treat it in colour on the canvas, but not on the print. It was a scene such as this that earned for Andriotti his first fame as a painter.

No. 65, *The Common Lot of Mortals*, is a well-taken but gruesome subject, an interior with figures, and on the bed in the corner lies a woman dying. No. 350 is a portrait by the same master; Mr. T. C. Turner, and is in a much happier, if more ordinary, style, and equal in technique to his other work.

Mr. John Bushby has several pleasing subjects. No. 75 is one; No. 109, *From the Desert*, another; and No. 140 a third.

Mr. J. A. Hodges has a lovely composition in No. 76, *A Scottish Loch*, but this is his only exhibit.

Now we reach Mr. Hinton's first picture, No. 78, *Oyster Beds, West Mirsea*. Essentially a cloud study, everything is subdued to force the sky, which is quite beautiful enough to take the burden of attention upon itself. This is rather a favourite treatment of Mr. Hinton's, and his little book on *Practical Pictorial Photography* gives a similar scene, and shows how it is done.

No. 113, which has been called *Sun Breezes*, is spoilt by a light cloud, which catches the eye and misses an otherwise beautiful and characteristic subject, which is in the best style of the worker.

No. 193, *Silent Gladness*, is disproportionate—artificial and palpably sunned down; the tangled undergrowth is quite overweighted by the heavy trees above, and the whole has an unreal look about it that is not convincing, either photographically or artistically.

No. 89, by Mr. C. C. Branch, is a gloriously lighted subject, as one might expect in the land of camels and drawers of water.

Mr. W. D. Welford also sends a study in lighting; his idea is good. In his mill scene (No. 93) he surrounds with light the dark mill and foreground. The only practical methods of gaining the maximum effect with the minimum of labour are those with which Turner startled his contemporary by putting a dark castle bang against the light, and right in the centre of the picture (Cellar, National Gallery). Mr. Welford's other picture (No. 101), *Telford Bridge*, is also a nice composition, but neither of them is as ambitious as we should expect from this past grand master of photography.

Mr. Percy S. Lankester sends in another of his halated-tree-trunk-reflection-in-the-pool studies, for which we have no sympathy; we want to see something better from you, Mr. Lankester—you can do it; let it be done.

The works of Bolas should be above criticism; two of them are, but the third, which is illustrated in the catalogue, No. 201, is harsh, and white, and square, and ugly, and why it has been put amongst the reproductions we know not.

The architectural subjects are throughout very fine, and, we will take em collectively rather than individually, as near perfection as photographic process can make them, Mr. Gash's work, that of Mr. H. W. Bennett and Mr. C. J. Fowler being particularly admired, to say nothing of the prize print of *Wirksworth Church* by Mr. Bland. By the way, Mr. Bland, are not sunbeams penetrating through a stained-glass window, as at *Wirksworth*, always parallel?

Miss Lovibond's delicate little studies, too, were greatly liked, and Mr. J. H. Avery's *Entrance to the West Door, Lichfield*, was the subject of universal comment.

Mr. John H. Gash has aroused public opinion on his medal picture (No. 130). At first we were inclined to find fault with the award, but, on studying the matter more deeply, we have come to the conclusion that the Judges were not far out. To surround a bright (though perhaps in the print forced) light by dark and subtle shades running in straight lines is a canon of art not fully learned yet by the average photographer (forgive us for speaking so plainly). The selection of the subject is happy and the main idea well developed—again forgive the word. Some say the shadows are slanty and harsh, but look how nicely they are treated and balanced; the eye is led unwittingly from point to point, and is able to jump the apparent obstacle without feeling the "jolt." The light and shade are exquisite—no detail too subdued and yet not too prominent. Yes, we think the award not out of place, all things considered, and we say so because we looked carefully round the room to find a better picture, and, like the man who tried to jump into his pyjamas on the clothes line, we signally failed to do it.

The Liverpoolian, C. F. Inston, is next on the list; he has again got a medal, and no fault can be found with this unless it is the fact that his prize picture is a little like and more perfect than the one that got the medal last year. *The End of a Stormy Day* (No. 148) is very truthful, but his medal picture (No. 191) is luminous in the extreme, and the delicacy of the clouds and perfect rendering of the sea leave no doubt as to the merits of the picture. Mr. Inston sends some head studies, which indicates that he is extending his choice of subject, and we shall look for something equally good from him next year, only in another field. His *Sheep Study in Winter* (No. 162) is also very good. There is no "fake" about this exhibitor's work; he is honest, and has the courage of his convictions.

Mr. Rudolph Eickemeyer, junr., sent two examples of his versatility. No. 140, *When the Daylight Dies*, is the same as exhibited at the Salon, and we heard one gentleman's remark on the subject that was rather funny, and perhaps a little unkind. He said the title ought to be "When Judson Dyes." The other picture (No. 226) is one of the daintiest bits in the Gallery. *The Dancing Children* are dainty, the composition and lighting are dainty, and the work itself is daintily executed. The interior is in the artistic style depicted by Haynes Williams—we will not say Maud Goodman.

No. 174, *A Fair Artist*, by H. Stuart—his only exhibit—is a sunny bit of work, and looks all the more vivid in being hung next Mr. Page Croft's *December*.

The sunlight studies of Mr. C. Keith Humphreys are also well rendered, particularly No. 181, *A Sun Bath*.

Mr. J. Kearney, junr., has many exhibits; in point of numbers, taking individual prints, he has the maximum, many of them good, particularly his sheep studies (No. 182); but why mount them all in one longitudinal mount when the "light line" in each print varies to such an extent as to be positively painful at a short distance, and utterly spoils the whole? Individually mounted in the same manner, the prints would be immeasurably improved. Mr. Kearney is still a votary of the "lamp-post" school, vide his *City Mists* (No. 221) and No. 269; but his *Woodland Sunshine* (No. 254) is his best effort. The shadows on the tree-trunk are not only truthfully, but artistically, done.

Mr. Thomas is represented by two works only, one in his usual picturesque birch and-bracken style (No. 188), rather flatter than usual, but very beautiful, and the other (No. 271), called *The Pool*, is anything but up to this gentleman's standard of excellence. It is the hackneyed scene in the Pool of London, with the same old steamer on the left, and the same old cloud above, and the same old softened-down Tower Bridge in the distance, made a little more misty and softer than usual to tone down the harsh light, but still the view that we get in everybody's guide-book to London.

No. 189, *Fruit*, by J. M. Whitehead, and his medal picture of *Roses* (No. 276), came in for considerable attention, opinions as to the award flowing freely from the mouths of various critics whose opinion on such matters is looked upon as authoritative; but we admired the work, and, whatever is said about it, it is certainly very fine, if not worthy of a medal.

There can be no two opinions on Mr. J. H. Gear's carbon print reproduced in the catalogue. There is only one description for it; it is "Leadereesque."

Mr. Rawlings' pictures, too, should not be overlooked. No. 99 is like Mr. Hinton's scene of the same subject last year at the Salon, which it equals in artistic merit, and No. 259 may be judged from the illustration in the catalogue.

*Ancestral Trees* (No. 218), by A. G. Lawson, is a very sunny beech-tree picture, and we should like to see a few more of his pictorial results.

Mr. Vivian Hyde's work is, as usual, uniformly good. His first picture, No. 161, *Where Rushes Grow*, is delightful in its quiet tones, and the straight lines of sky and foreground are so nicely harmonised that they fail to obtrude unduly—a difficult subject for a photograph, but very ably treated by Mr. Hyde. No. 205, *Fishing Smacks Leaving Harbour*, speaks for itself through the catalogue, where its artistic qualities need no comment from our pen. No. 211, *A Surrey Lane*, we like least, though this is by no means a bad subject; and No. 260, *A Surrey Mill-pond*, should not be passed by.

*The Verge of Day*, by Mr. Bertram C. Wickison, is another beautiful landscape. We are not sure about those reflections with the deep-toned bank and dark tree trunks. The water beneath should be darker also; if one part is reflected, so must the other be if in an exactly similar position. There are signs of treatment, too, in other places, which give the wanting touch to relieve the flatness in the shadows; but that touch is so artistically done that we had better not question its legality.

No. 219, by Philipp Ritter von Schoeller, is one of the little gems of the year, the reproduction being about "life size." What "sentimental" thoughts this little half-tilted boat near the sand dune by the sunlit sea conjures up in our memories. Peace, too, reigns here supreme, and, as we gaze at it for a moment, our thoughts get lost upon that quiet little seashore, and we are lulled into forgetfulness by the soft lapping of the waves, oblivious to the present and the exigencies thereof. Such is the power of sentiment over the captious critic. This gentleman with the long name has several other exhibits, but none of them so fine as this.

No. 227, by the G.O.M. of photography, is also illustrated in that wonderful catalogue. The picture speaks well for the unabated vigour of its producer, but we could almost wish for the sequel picture. Perhaps we shall get it—let us hope so—next year.

No. 238, see catalogue again; a fine study by Oscar Hardee of *Silver Birches*.

No. 241, by W. A. J. Hensler, is a good mud-flat study. This gentleman's work is excellent throughout, and his print, No. 267, specially good, though too much foreground is shown.

No. 275, *The Glow of Summer Noon*, by Mr. J. S. Mummery, appeals to us at once, and has been much admired by all with whom we have spoken of it. It is a difficult subject to treat, but the lines are well broken by the shadows and figures, the posing of the latter being most unconventional.

The "Romney" portrait (No. 303) by Mr. Walter Monro, is at once an ambitious and artistic effort; moreover, it is successful, and those who are acquainted with the artist's picture will notice that the likeness is strikingly like the original.

#### THE TECHNICAL SECTION.

The thirty odd exhibits in the Technical Section are of very great interest. Mr. Sandland's *Lion at the Zoo* (No. 331) shows the king of beasts in a most natural attitude. The Autotype Company contribute several facsimile copies of Rembrandt etchings in photogravure (No. 332), and some collotypic illustrations in colour for Lord Armstrong's book, *Electric Movement in Air and Water*, and a splendidly produced carbon enlargement of a negative by the Rev. C. J. Moncrieff-Smyth of *St. William's Hostel, York*. Father Smyth's negative is an uncommonly good one, and the enlargement does it every justice. For a copy of an etching made by "allowing green or yellow light to fall upon bromide or Alpha paper, placed with the sensitive face in close contact with the picture copied, the bromide paper lying interposed between the light and the picture," Mr. J. Hort Player takes a medal. He has half-a-dozen examples of this interesting process. *Rainbows in the Skies* (No. 341) is Mr. William Andrews' exhibit. The photographs "show that the tint of the sky is lighter inside the bow than the outside. One of the prints also shows the secondary or outer bow." These photographs are of interest as elucidating some of the little-understood phenomena of rainbows. Mrs. Walter Bersey (No. 350), a large portrait by Mr. T. O. Turner, gives him an opportunity of showing his skill in this class of work, but Mr. Turner's powers have not yet been fully demonstrated at Pall Mall. Kodak, Limited, exhibit three enlargements, showing the effects of enlarging through bolting cloth: "(a) Enlargement on smooth Royal

bromide paper without bolting cloth; (b) a similar enlargement with bolting cloth in close contact with the surface of the bromide paper; (c) a similar enlargement with the bolting cloth at a distance of three-eighths of an inch from the surface of the bromide paper; (d) a contact print from the negative from which the foregoing enlargements were made."

Three Lippmann photographs emanate from Mr. E. Senior, though we doubt if they will be properly seen in the position in which they have been placed. There is a picture of the *Eclipse of the Sun as Seen at Quetta* in 1898, by Mr. Fred Bremner, showing the disc surrounded by a mass of clouds. Other exhibits of scientific and pictorial interest also figure in the section. In the lantern-slide department, half a dozen Joly coloured transparencies of flowers by Miss Alice Worsley, the best results we have so far seen by this process. Other contributors of lantern slides are Miss Acland (portraits), Messrs. Malby (flowers), Graystone Bird, Kearney & Kelsey; but the glory appears to have departed from this part of the Exhibition. General E. F. Lloyd is responsible for a dozen carefully prepared stereoscopic transparencies, although personally we should have preferred them in a warm rather than a dark colour.

#### THE APPARATUS SECTION.

Most of the exhibits in the Apparatus Section have recently been fully described in our columns. Messrs. Houghton show an adaptation of the principle of the Sanderson front to hand camera, and Lloyd's rotary print-trimmer, which is said to give clean and true edges to a print without buckling it. Among Messrs. Watson's exhibits are the Gambier Bolton hand camera, the Binocular stereoscopic camera, and the Kromaz colour apparatus. The Tella Camera Company show the latest form of this admired instrument, and Mr. Thomas Webster a printing frame, which allows of the whole of the picture to be seen at once, and a simple little flash lamp. For one of a series of original engraved screen plates, Messrs. J. E. Johnson & Co. take a medal, the ruling being 200 lines to the inch. Zenith cameras and the folding pocket Kodak camera are exhibited by Kodak, Limited. Mr. E. Sanger Shepherd's exhibits include examples of tricolour photographic printing in transparent media, a set of light filters for the work (for which he receives a medal), and the Cadett light filters, Mr. Cadett himself being responsible for a colour sensitizer and orthochromatic plate standardiser, "an instrument which, by means of diffused light passing through adjustable openings and selected colour media and a series of diaphragms to the sensitive plate, affords an easy method of testing orthochromatism, and the safe light glass for the spectrum plate."

Messrs. Mackenzie & Co., of Glasgow show a daylight slide which enables dry plates or films, when placed in the envelopes provided, to be changed in daylight. "The envelope is of a stiff, light-proof cloth, in two parts, and is laid within the slide upon the shutter. The shutter has a groove which engages with a prominence upon the flap of the envelope, so that, when the shutter is drawn, the flap of the envelope is drawn from over the plate with it. There is an opening in the back of the slide covered with celluloid, through which may be seen whether the envelope flap is working properly, and any number upon the envelope. After exposure, the shutter is closed, the same action closing the flap of the envelope, which, with the plate inside, may then be removed, and another inserted in its place."

Messrs. Marion's exhibit comprises the Massey field and studio stand; the Perfect developing dish; the Sectional print-washer; the "Soho" circle print trimmer; a new form of the Hurter & Driffield actinograph; a film-holder to support films during development; a tripod stay; and the speed-testing printing frame, which is a printing frame of the usual type provided with six narrow shutters side by side for the exposure of the plate in strips.

The Cyko camera, No. 4, is shown by Messrs. John J. Griffin & Sons, who also send a frame of curious effects obtained with kaolin. An adjustable vignetting apparatus comes from Mr. Charles S. Southin. "It consists of two light frames of wood and metal, the lower or metal frame being attached to the printing frame by means of a clasp and mill-headed fixing screw, and having a horizontal movement across the printing frame. The top wood frame, which carries the vignetting card, has a movement in a transverse direction to the bottom plate, and can be raised or lowered to any angle or height by means of screwed studs and nuts and a spring. A light-diffuser is attached to the top frame." The Secco Film Company send two capital negatives on Secco films, and prints from negatives made on Secco films and Messrs. Spratt Bros. a 10 x 8 long-focus light field camera and three backs, and a whole-plate long-focus light field camera and stand. Metzograph screens for graining photographs are sent by Mr. James Wheeler, who also exhibits results obtained by his method.

#### THE PHOTOGRAPHIC SALON.

UPON one feature of the Seventh Exhibition of the Photographic Salon we unhesitatingly congratulate those who are responsible for bringing together the collection of photographs and other things which are now to be seen at the Dudley Gallery, Piccadilly. We allude to the omission from the catalogue of the so-called Forewords which, in the six previous issues of the compilation, prefaced the list of exhibits.

This precious deliverance, which varied slightly in manner, but scarcely in matter, from year to year, must be held responsible for a great deal of the ridicule and contempt which the principal photographic and non-photographic newspapers and reviews in Great Britain have always cast at the Salon. Condensed in meaning and teaching, these monumentally stupid Forewords asked people to believe that pictorial photography did not exist before 1893; that the Salon was the only place where pictorial photographs were shown; that all the exhibits there betrayed evidences of personal control and inspiration; that they were produced in virtue of a boasted ignorance of optics, chemistry, and the "mechanics" (*sic*) of photography, &c. If all, or any, of this balderdash were true, then a "photographic" Salon, which ostentatiously went out of its way to belittle, if not to deny, the paramount aid of photography in the production of its exhibits, was a sham in name, if not in essence. The word "photography" had no business to be used at all in such a connexion.

The suppression of these silly and harmful forewords should disarm a great deal of the opposition they always provoked, and must be regarded as a tacit admission by the Salon folk that the contempt previously shown for photographic knowledge in pictorial work was an indefensible piece of folly which they are now anxious to wipe out. It is indeed fortunate for the present Exhibition that the Forewords have been abolished, otherwise we should have had the curious sight of a conflict between theory and practice, the Forewords calling the Salon Exhibition one thing, the Exhibition itself silently, but none the less effectively, showing that it was partly something else altogether.

For this year's Salon is a mixture of exhibits which are obviously photographs and other things of which the method of production affords scope for a considerable amount of guesswork. On the one hand, exhibitors such as Mr. Annan, Mr. Baker, Mr. Bright, Mr. Cameron, Mr. Hubert Elliott, Mr. F. H. Evans, Mr. Greatbach, Mr. Greger, Mr. Histed, Mr. Lankester, Mr. Ralph Robinson, Mr. H. P. Robinson, Mr. Leyton Scott, Mr. W. J. Warren, Mr. Wellington, and others, show us results in which it is easy to trace the predominating influence of the knowledge of how to use a lens, expose a plate, develop a negative, strike a print, and yet secure a pictorial result. Be it ever so pictorial, the photograph is there.

But, when we turn to many of the gum and other prints in the room, we are met by the obvious fact that their producers have strenuously sought to conceal their source of origin. You are conscious that attempts have been made to imitate charcoal drawings, stippling, etching, and water-colour work; and that, while these attempts have only met with partial success, and in some cases are mere burlesques of the real thing, the photography of the work is unmistakably bad. The exercise of the much-desiderated personal control has introduced distortion of outline and perspective and destruction of structure, the laws of lighting have been set at defiance, tone values falsified, and definition subdued beyond all recognisability of subject. This is not good photography.

The Salon, in fact, this year is a double Exhibition—photographic and non-photographic, and the results shown automatically classify themselves under two heads. If this sort of thing continues, would it not be well in future for the Salon to go in for a technical as well as a "pictorial" section? Then we should know where we were. At present we are asked to admire two sets of productions—good photographs and bad photographs, or, at least, to regard them from two standpoints in diametrical opposition. Clearly the Salon is a "photographic" Exhibition or it is not; in either case, half the work shown this year is out of place; but, if in future would-be exhibitors are asked to specify how their pictures are to be classified, "technical" or "pictorial," the present difficulty would be easily got over, and in that case the Salon would, doubtless, appoint technical and pictorial selecting committees. Who knows?

This year we have an artificial striving after pictorial effect that is, at times, ludicrous. One ingenious gentleman, a very clever experimentalist no doubt, gives us:—Two Brown Studies, A Puzzle in Indigo, A Villa in Green Gum, and A Study in Coloured Chalks. They are, some of them, very nice indeed—very picturesque, full of feeling—but in our humble opinion, in certain instances, they are utterly without the bounds of legitimate photography. Let us take a few examples of well-known

workers from the catalogue and analyse them indiscriminately, contrasting here and there the good, bad, and indifferent.

The first name of note is that of Robert Démachy, whose work is so well-known to our readers that they will readily follow our criticisms. His eleven exhibits are in excellent taste, but some naturally appeal to us more than others. His first exhibit, No. 2, is in the red chalk style with semicircular mount. *A Child* is no title at all, but is sufficient to indicate that the print contains a figure, in this instance not the graceful model that we are accustomed to from this exhibitor. The child is laying at full length in an uncomfortable attitude, with a look of abject fear on its face quite unlike what one expects, except in the work of such exhibitors as Mr. F. Holland Day.

Mr. Démachy's next study (No. 7) is more charming. *Première Communicante* (No. 15) is full of expression and feeling, and shows us that the French model is far superior to the usual stiff and hard-hearted English dummy. No. 20 is also a very pleasing study of a market girl (the model free from self-consciousness again), and No. 31, *A Fishing Boat*, shows Mr. Démachy in an entirely different light. Here is motion in the boat and waves, and one feels at once, instinctively, what the artist intended to convey—like the boat pictures of the late Edwin Ellis, which it much resembles in treatment—this is, at once, broadly and freely treated, yet nothing is lost in the effort. Again Mr. Démachy's versatility is noticeable, for next is a delightful little head (beautifully framed too), and further on a portrait (No. 99), and, again (No. 106), *La Malmconia*, and several others. No. 123, a portrait in the open air of a girl with pampas grass, is rather spoilt by the dark figure against the light glass, and, as this is placed close to a charming picture (No. 125) by Mr. Ralph Robinson, the defect is the more noticeable.

Next, following the names in the catalogue, comes *Spring*, by an American contributor, Mr. Clarence H. White. He divides his picture, that of a female—a la Albert Moore—in a garden of spray blossoms, into three parts, putting the lady in the centre and blossoms in separate panels on either side; the subject is good and nicely treated, but it is old, and the price (71.) including the ingenious mounting and framing somewhat heavy. Mr. White's other pictures, Nos. 114 and 174, are worthy of more than passing recognition. Mr. Will Cadby's work follows; and, if No. 6 is a true rendering of his landlady, we are sorry for him, and for her, poor woman; we should also think her dear at the price, viz., 10s. 6d., for she is very infirm, very chalky, and very ugly.

*Swiss Hay Sledges* (No. 29) is another that we cannot for the life of us either understand or appreciate; picture a snow hill, and silhouetted against it in black what look like a removal pantechnicon with black horses and black figures at more or less regular intervals. This may be a gum effect, but whatever it is called or intended to represent we neither know nor care, we can only say that, like gum, it sticks very unpleasantly. No. 84 is better, but it resembles a slight sketch of a snow scene, done, as we heard a passing critic remark, "with a stump and chalk." No. 158, *A Snow-shoveller*, is another "crayon" study, and we should recommend Mr. Cadby to bury his models as quickly as possible and find others, for a thing of beauty is a joy for ever. How about a thing of ugliness? Is it art? is it photography?

No. 10, *Cigarettes* (a sketch for a poster), by Clement Hopkins, is a black-and-white figure, whose arms, body, and legs are all apparently in uncomfortable and grotesque attitudes. Perhaps it was originally intended for the potency of So-and-So's "Special Scotch," but the perpetrator did not like to give his friend away, so he altered the title. Again, we say, Is this art or photography, or artistic photography, or utilitarian eccentricity?

No. 47, *Puss in the Corner*—a study in red chalk. The kitten days seem over; the figure is ugly in pose, and her attitude might have been suggested by the more graceful "French" picture *Le Souris*. The foreign element is much to the fore this season, and we cannot but admire some of the strangers' clever work, and suggest that our own countrymen might condescend to take a lesson occasionally therefrom.

Mr. Puyo's work is in his usual characteristic and artistic style—his maidens three—whether under the title of *panneau décoratif*, and whether singly or taken together, are always delicately taken, exquisitely, though perhaps not always truthfully, lighted and charmingly treated.

We should like to, but we cannot, say so much for the work of Mrs. Kasebier; it is more eccentric. Her models are not as beautiful as butterflies; her tones are dark, and a feeling of deep melancholy pervades one's inner consciousness as one gazes on the sad faces of her subjects; yet this lady's works are lifted above the plane of mediocrity by the originality of their composition and treatment. Her picture (No. 127), *Mother and Children*, is particularly well done, and we should like to see more of it. The tones are lighter; that intense blackness which we

notice in many of the pictures this year, and which seems to be the prevailing craze, is not so noticeable in this clever lady's last-mentioned work. No. 12, *Sous Bois*, is a luminous treatment of the parallel tree subject. It has most of the good qualities and few of the bad ones for a picture of its kind.

The work of Mr. Eustace Calland is somewhat disappointing. No. 13 is, perhaps, his best, and is a light treatment of a landscape similar to those exhibited some years ago by Mr. G. H. Boughton at the Royal Academy. No. 78, *At Twickenham Ferry*, is a good imitation of a bad black chalk drawing, a very black chalk drawing, and where the ferry is we don't know; but this print was mounted on a larger white mount, which completely smothered it. It was altogether unworthy of Mr. Calland's reputation. No. 151 was nearly as bad, horrid straight black lines running right across the picture from the bottom left-hand to the top right-hand corner, dense black masses of trees, no delicacy, only glutinous gum. Stick not to the modern craze of anti-photographic processes is our advice to those about to photograph anew.

No. 24, *A Normandy Road*, by Mr. C. H. L. Emanuel, is a somewhat similar subject.

No. 44, *A Portrait of Sir W. B. Richmond*, is a clever bit of work, as is also No. 172; but the latter is sadly over-mounted.

No. 51, *The Willows*, by Miss M. Devens, looks very pretty in its red chalk and nice gold frame; and No. 52, *La Cigale*, is also a drawing-room article *de vertu* in blue and gold, strongly reminiscent of the Flaxman style of decoration.

No. 58, *Wind and Rain*, by Charles Moss, is really excellent and full of artistic feeling; but why not do it in charcoal at once? This applies to many of the photographs so called, that hang on the walls of the Salon. No. 148 is another by the same gentleman, only of the mud-flat school, which it very closely copies; and No. 225 is another worth noticing *en passant*.

Prices are high this session. Mr. F. W. Birchall has a weird and mystic subject (No. 55), called *The Trinity of the Dawn*, price 12l. 12s. We are not sure whether the picture was hung so high on account of the price, but it is in the sacred corner of religious art—the most expensive corner, by the way, in the show for its size. Three prints. Total cost, twenty-four guineas. Things must be good for those amateurs that devote themselves to religious mysticism.

The further we go the more gum we get. Mr. George Davison is devoted to it. No. 60, *Night and Morning*, is a black-and-white treatment. In the distance, white (dirty white) robed choir boys in the nearer distance, or foreground, are what appeared to be very large notes of interrogation, but what, on closer inspection, were found to be men in rather crooked postures—black men, white boys—title, *Black and White*. Mr. Davison had a lot of these dark and dirty-looking pictures, that appeal neither to the photographer proper, nor (rarely indeed) to the artist, unless of the pronounced new English style, or of Whistlerian school. Look, for example, at No. 66 and at No. 116. If this is photography, let us play at painting and call it art. *Boulogne Quay* (No. 138) is certainly very finely rendered, but gives one the "blinks" to look at it for long; and No. 146, *Hayling Island*, is also an exception to the above rule.

No. 64, *Auld Reekie*, by Mr. Ralph Robinson, brings us to the other side of the subject, and we must congratulate Mr. Robinson, senior, on having such an apt pupil, a real chip off the old block, for his work is always artistic, careful, and most perfect in technique. This picture is somewhat weird perhaps, but leaves no doubt on the mind of the spectator of its "motif." Let us carefully follow Mr. Robinson's other work, which we can always do with advantage. No. 109, *Heads of a Girl*, are all graceful head studies, tastefully mounted and framed, quite a harmony in brown. The only fault we can find, collectively, is with the lighting on the arms, which makes parallel lines of the arms of the two figures on the left, and this is rather emphasised by the third arm being posed and lighted in the same way, but in the contrary direction. Individually mounted, this would not, of course, be noticed. Still, the three heads are exceedingly beautiful. No. 125 is another fine example. The perfect rendering of the face and figure dead against the light without halation, and the interposition of the black hat, are triumphs of the photographer's skill and artistic ability. No. 143, *Portrait of a Clergyman*, is all right photographically, but the man of the cloth looks very ill at ease, and as if he had something under his coat that he would very much like to get rid of without being detected in the act. No. 167, *La Penseuse*, is also characteristic of the worker, but the lopping off of half the head and figure seemed a pity to us. No. 171, *In an Old Window*, looks like a smaller study, on similar lines, to last year's picture of the same subject; and here we might refer to the picture by

Mr. Robinsen, senior, viz., No. 91, *Old Dapple*. The picture of a fine horse standing squarely on its legs, the envy, admiration, and delight of the bystanders, who are posed in the way familiar to us in our veteran's earlier works. The picture is taken on one negative direct, and is worthy of a high place in the collection of its able producer.

Of Mr. Greatbatch's work, No. 68, *The Ford*, looks rather on the slant, but No. 192, *In Winter's Garb*, reminds us of a similar scene entitled *Chill October*, exhibited a year or two ago at a local Exhibition—we forget by whom—but the two subjects are precisely alike; the one was a painting in oils, whilst this is an excellent photograph.

The Hon. Secretary is represented by two works, Nos. 69 and 83, both of them fair samples of the advanced style of portraiture; yet Mr. Craigie seems terribly afraid of getting a little too much detail or definition, and we do not consider his work equal to that of last year. No. 74, by Heinrich Kühn, is a solitary example by this clever operator, and we are sorry to note the fact. The title is almost sufficient to indicate the nature of the study (even to English ears). The picture is very sunny, a little too subdued, perhaps, considering the amount of light and shade, and also marred by the fact that the bold clouds contain a caricature of a face which is exceedingly unfortunate for exhibit and exhibitor, alike, for a blemish like this, once seen, grows on one and obtrudes to such an extent as to become painful.

No. 75 is another blue or green gum picture from the brush of Hans Wazek. This, again, is more pictorial than photographic, though very full of feeling as a work of art. There is another, but not nearly so nice, and with much more Prussian blue and indigo in it; this is No. 227, and may well be passed over without comment.

Baron A. von Meyer is not by any means so well represented this year as last. His portrait in the style of the old masters is by far his best picture, but we presume he has not had the leisure to devote to this favourite hobby, owing to his recent marriage.

No. 85 was one of the best portrait pictures in the show. The catalogue says it is a portrait of *Miss Bourke*, daughter of *Hon. Mrs. Edward Bourke*; but, whoever she may be, she has a sweet face and a beautiful figure, which are shown off very effectively, and spoilt only by being contrasted with a very conventional stained-glass window, the pattern of which will catch the eye in spite of the other and more beautiful attractions of the print. This is the work of Mr. Robert Johnson, who also shows a portrait of *Mrs. H. Beerbohm Tree* (No. 95) and the *Study of a Girl's Head* (No. 219).

No. 86, *Evening on the Lune*, is by Mr. Alex. Keighley. This is a dreamy, misty, in-the-gloaming kind of river scene, where "the shades of night are falling fast," and all is subdued and peaceful, even the ripple on the water might be mistaken for a moonbeam that had got lost and gone astray, and was struggling to find its way back to its original source again. The ancient-looking hostel in the distance could not be associated with the modern and hideous river-side pub., such is the artistic treatment of the picture, and, if the details are occasionally somewhat wobbly, we must appreciate the poetic desire of the exhibitor whose work generally meets with universal approbation.

No. 94, *Dutch Fisher Folk*, is also good, somewhat low in tone, perhaps, and a little flat, but the composition is excellent, the positions of the figures (taken just at the right moment) give immense relief to the scene which rather follows in the footsteps of the French school of "under-tones." Mr. Keighley has evident flights of poetic fancy. *An Old Viaduct* (No. 96) is another example of this—not that we decry poetic treatment; on the contrary, this is particularly successful and we like it, and *An Old Viaduct* appeals to our senses in the way we hope its exhibitor intended it should, the only thing we would wish to impress upon the general workers of this school is, Don't overdo it; ambition to be artistic—practically artistic—is a great ambition, but it is not always practicable, particularly when limited by technique, such as the requirements of photography demand.

We are sorry not to see more of Mr. Percy Lund's work. No. 101, a nude figure, is not up to the standard expected from Mr. Lund, but this is amply atoned for by No. 232, entitled *Halcyon Days*, a figure study in the operator's best pastoral style. The brown canvas mount, too, is in perfect harmony with the print and frame.

Next we come to the work of Mr. A. Horsley Hinton. No. 105, *Gorse Bloom*, is not in the artist's happiest vein. A large and picturesque sunlit mass of cloud floats over a gorse-covered landscape; but somehow the landscape and the cloud do not appear to fit each other in the way usually associated with the exhibitor's best work. The cloud in itself is perfect; the landscape has been made to support it, but it comes in badly somehow; there is a fitful gleam of light on a corner of the gorse, and a fuzzy, sunned-down, artificial appearance about the rest of the

foreground and middle distance that detracts from the value of the work as a whole; yet we must not condemn the picture unduly, as we know the exhibitor was very pushed for time, and could not give his work the care and attention it needed to bring it nearer perfection and nearer the operator's own standpoint. No. 197, *By the River*, is much better; in fact, there is little to be desired in this work, it is truer and less artificial-looking. The tall trees are characteristically wrought, the light leaving the sky as it does helps to bring these trees in bolder contrast against the smaller ones, thus giving a greater effect of "breadth" to the whole than would otherwise have been the case. The beautiful well-lighted foreground assists in no small measure in imparting a strong interest to the subject, and at the same time gives value to the distance by contrast. That the lights have been lightened or the darks darkened to attain the ends of the artist may or may not be true, yet the effect is very striking, the only apparent triviality that has escaped the lynx eye of the exhibitor is the "undarkened" patch of half light in the immediate foreground, a fault so trivial that it is hardly worth while recording. No. 206, *After Rain*, is again not so pleasing. It is weaker in treatment, lacking in interest; particularly is this noticeable between the trees and the bottom of the picture; there is also a fuzzy look, as if the work had been sunned down all over, losing that "crisp glisten" that one sees "after rain," and which, we admit, is very difficult to obtain in an artistic manner in photography or in painting. The introduction of cattle, figures, or sheep, would help the picture somewhat; but we are not in love with the scene, and pass on to the next, which is No. 214. *In a Yorkshire Glen* is more on a par with his last but one, and resembles in choice of scene one of his pictures exhibited here last year. The rugged and mountainous path, lighted with the object of throwing the huge stones into greater prominence, the tangled trees dark against the high sky line, all help to make a romantic picture; the only thing one misses is a connecting link of distant hill to bridge the distance between the trees right and left, a scheme Mr. Hinton introduced, if we remember rightly, in his last year's picture.

Mr. W. Thomas is only represented by two works this year, Nos. 107 and 153. *The Mill Dyke* is good and slightly out of Mr. Thomas's usual style, but his *Woodland Glade* is not up to the standard of perfection one naturally expects from such an experienced worker. Nor are Mr. J. B. B. Wellington's subjects (Nos. 92, 108, and 189) as good as usual. They are somewhat black and harsh. Mr. Wellington has done, and can do, much better work than this.

Viscount Maitland is not so well represented as hitherto. *A Flooded Road*, No. 88, is a very fine piece of work, but his other subjects do not appeal to us, although his *Sunset* (No. 168) if it were a painting, might do so.

No. 180 is a nice little portrait study by Sidney Herbert, but the one next to it, No. 131, *A Study in Flesh Tints*, is peculiar both in style and treatment.

Mr. Harold Baker sends five pictures this year. An excellent portrait of S. H. Baker, Esq., R.E. (137), another portrait of the Countess of Warwick (142), a clergyman who looks very ill (143), a most important and very fine study in costume of Mr. Scott Baist. The latter is a triumph of posing, lighting, and technical skill, and is undoubtedly Mr. Baker's best effort. His last exhibit, No. 191, *But let my one feet never fail To walk the studious cloisters pale*, is also extremely well done—it is both artistic and technically good. No. 182, *In the Jasmine Tower, Agra*, by Mr. E. R. Ashton, is a work to which the same remarks apply.

Mr. W. J. Warren's pictures, too, deserve careful attention. No. 186, *The Man in Armour*, is, as its title implies, a man in armour; it is only small, but good; rather over-framed if anything, yet this keeps the strong light out—perhaps the idea of the exhibitor. No. 215 looks very like a Whitby stranded boat scene—has a long foreground and a subdued artistic atmosphere about it that is rather taking, and No. 246 was a portrait of S. W.

No. 200, by Walter Bennington, helped to throw up Mr. Hinton's picture, close by, very considerably. For those who have plenty of time, and a little ingenuity it will afford them an opportunity for exercising the latter quality in trying to identify the nature of the things represented by white blobs spotted over the foreground and middle distance of this picture. To give the artist his due, the lines of the composition are rather nice, but the execution!—well, three white dots and a smear don't make a foreground, nor do four fat finger marks and a black line make a tree.

No. 205, *The Black Cat*, by Mrs. Cabot, would sound better if called *Le Chat Noir*, and look equally well, for it was not a bad idea.

The portraits of Histed are, without exception, excellent. There are five of them—Nos. 216, 223, 234, 241, and 256—and they should be care-

fully studied, as well as Mr. Craig Annan's sole exhibit, the portrait of Mr. Orchardson, the artist. Alas! that we have not more "Orchardsons" and more "Annans" in this gallery. It was universally admired; even from the most "progressive" exhibitor down to the humble critic, all vied with each other in praising the portrait of the show.

No. 243 was as good a "game" study as any in the room, but the "young lady" was "prepossessing."

A rather rich treatment, somewhat resembling a dry-point etching, was noticeable in the picture of Mr. W. E. Dawson, No. 253, *A Birch Glade in Sherwood Forest*. The velvety black foliage against the yellow-toned sky was an effective arrangement.

### OZOTYPE.

On my return from a holiday, I have just come across your issue of August 18, containing a letter from an American correspondent, Mr. Colin Napier, relating to "Ozotype." I am sorry to say that in nearly all the working instructions with regard to this process which have been published unauthoritatively the writers do not strictly adhere to the method of working I laid down in my paper before the Royal Photographic Society, and so experimenters are led into error.

In my opinion the principal cause of failure is soaking the carbon tissue too long in the acetic solution, and the omission to thoroughly surface-dry the squeezed print and tissue between blotting-paper before hanging up to dry. It is astonishing what a small quantity of acetic solution is required. The temperature of the acetic solution should be between 65° and 75° F. for smooth paper. The carbon tissue should be immersed for one minute when soft tissue is used, and for one and a half minutes for hard tissue. At the expiration of this time the print should be brought in contact with the carbon tissue under the surface of the solution (of course avoiding air bubbles), and the two, clinging together, withdrawn at once, this operation lasting about ten seconds. Squeeze and surface-dry as soon as possible, and hang up to dry. When dry, immerse in cold water for twenty to thirty minutes, and develop in water at about 106° F. Glycerine added to the acetic solution will be found of great advantage. A good formula for ordinary rather plucky negatives is:—

Water .....	40 oz.
Glacial acetic acid .....	1 drachm fluid.
Hydroquinone .....	15 to 20 grains.
Glycerine .....	2 drachms fluid.

Do not over-print.

I take this opportunity to enjoin experimenters to wait a little while. An improved sensitising solution and a special carbon tissue are being prepared, and, when everything is ready, those photographers who aim at producing artistic pictures in a permanent medium, of any colour and on any paper, will be surprised to find how easily it can be done.

THOS. MANLY.

### EXHIBITIONS AND EXHIBITORS.

[Abstract of a paper read before the Hackney Photographic Society.]

I HAVE often been asked by photographers, anxious to improve their pictorial work, what they should do, are books of any use, should they study other people's work? and so on. Well, really it is a very difficult question to answer. Some of our books are written by men who know what they are talking about, and the study of the pictures produced by our best workers is bound to repay can we but keep out of the sin of copying. I do not suppose any one would deliberately set himself to direct copying; what we have to avoid is too close an approximation of style and treatment. At the same time the scope of the pictorial photographer is not great, and there are not enough styles to go round, so that, if you do by chance find an opening for your taste in a similar direction to another worker, I should advise pursuing it with all your ability, rather than attempting to make a change. For instance, if birch-and-bracken subjects are to your taste, and you put forth all your efforts in that direction, do not change to architecture because Brown says you are imitating Jones. Considering the limitations of photography, some of the press outbursts on plagiarism are just a wee bit far-fetched, and, any way, you need not pay much attention to them. By all means get an absolutely original style if you can, and I should strongly advise this, were it not for the absolute impossibility of it.

Another piece of advice is to absolutely shut your ears against the hysterical technical photographer and his denunciation of "faking." He only wants you to be upon the same level as himself, and shorts if you mount a step higher on the ladder. What he can do to a negative or a print he terms "improvement;" what you can do beyond this he terms "faking." That is all there is in this cry of "faking." We all try to improve our results; we intensify, reduce, alter tones, and do hundreds

of things chemically, optically, mechanically, or any other "cally," so why not "fakeally?" To put it broadly, if a dab of dirt at a certain part will make an improvement, dab away; if a mark that is obtrusive can be removed by soap and water, wash it. What you do and how you do it matters to no one, the resulting print will still stand upon its merits. If what you do is an improvement, it cannot offend by obtrusiveness, and therefore it is right. The question of what is legitimate and what not, is a good subject for an evening's discussion at a society when the promised lecturer does not materialise, but it is not one that an earnest worker should even consider. It is a subject teeming with humorous possibilities of debate, but should be reserved for an evening's relaxation from photographic work.

One more point and I must leave the exhibitor. It is that each one should endeavour to assist the Hon. Secretary of the Exhibition, and to find excuses for him and his co-workers, rather than, as is usually the case, giving him a lot of trouble through carelessness, and doing no end of fault-finding in addition. We are apt to forget that the officials of an exhibition are, as a rule, unpaid voluntary workers, giving as much time as they can squeeze out of business hours in addition to all their spare time. I speak from the dual points of exhibitor and organizer, and know full well the faults on both sides. But I think there is less consideration shown by the exhibitor, and more by the official responsible for the exhibition. Exhibitors will not follow out rules, regulations, and instructions, and many troubles are thus caused. For instance, at a recent exhibition that I had charge of, a framed portrait arrived with absolutely nothing on back or front of frame, nothing on the wrapping paper to indicate who it came from, and the post-stamp was undecipherable. A month or two after I received a simply awful letter about gross carelessness, &c., &c.—you can easily fill in the &c.s.—which, after inquiry as to what the picture was like, turned out to be the one unlabelled. How on earth I was to deal with a picture like that, no title, no class, no sender's name, and not even the town it came from, I should like to know. I could give numerous examples of gross carelessness upon the part of exhibitors, leading to unpleasant letters and crossness all round.

Turning now to exhibitions themselves and questions connected therewith, we have recently had the matter of doing all one's own work put before us rather strongly. Your first thought will be that there is very little in this, but I think upon reflection you will find it is a many-sided question. Personally I admit that, within certain limits, I should not object to part of the work being done by other hands. It may now, I think, be safely held, that purely mechanical, or even skilfully technical, work, on its own merit, is but of little consequence without the evidence of personal taste and feeling. If the particular part of the work into which the individuality can be imparted is produced by the exhibitor, the other mechanical operations are simply necessary to complete. I presume the outcry is raised against such a thing as getting an enlargement done by a trade printer. If we take it, as we are entitled to, that the merit of the result was secured in the selection of the subject, the exposure and development of the plate, why should the mechanical operation of producing a print by some one else be wrong? We do not make our plates; why shouldn't that be insisted upon as well? We may place the print in the framer's hands and tell him to use his taste in selecting a suitable frame, why is that not objected to? Personally, I do all my own work, from exposing the plate to the framing, sometimes even to the making of the frame, and therefore it is a matter I can speak impartially about. If I were to take as illustration the making of the glass plate itself before coating with emulsion, possibly that would be going too far, as the manufacture of glass is not within the power of the ordinary photographer. But certainly the making of dry plates is within our power and province, yet no one appears to think this obligatory. Many of our ideas as to what is right start nowhere and end in the same locality. Why should we skip the making of the plate and paper, commence with exposure and end up with printing, leaving out also mounting and framing? These sort of definitions are very common in photography, and as arbitrary and reasonless as common.

But, on the other hand, I admit the chance of danger in giving a free hand to the exhibitor as to what he may get done for him. It is difficult for even a trade printer to make prints or enlargements without effecting some change. There can be but few workers who would not improve a result when the chance occurred, provided it did not entail much time or labour, and that would be wrong, of course. If we could ensure that the print produced by other hands would be always inferior to one produced by the exhibitor, all would be well. But we could not guarantee this, even with trade printers. To be a purely mechanical operation, there must be no element of uncertainty as to improving the result.

Therefore, although I do not see why we should be told where to start and where to leave off, to take a very practical view of the matter, the more the actual exhibitor is responsible for the work the better.

Another question, almost a periodically recurring one, is that of Judges and their qualifications, and, although it is rather a burning subject to tackle, a paper upon exhibitions would be incomplete without some reference to it. In photography we are rather curiously situated, and it difficult to make comparisons with other kinds of judges. Photography is started as a chemical, optical, and scientific study, and it is only of recent years that we have progressed far enough in the direction of the pictorial to make this latter a serious consideration. The consequence is

that we have many men fully conversant with all the scientific side, but very few of much account as pictorial workers. We have at our exhibitions Judges who have never tried their hands at pictorial work, who know very little about it, and some of whom are actually fond of parading their entire disbelief in the pictorial altogether. Yet it is held by many that, to appreciate pictorial merit in a photograph, a man need not of necessity be able to do the same work himself. It has been an article of belief for years amongst some, that a man can be a good judge of music without being a musician himself, or a good judge of painting without being able to paint. And these opinions are held by honest thinkers, and are therefore entitled to our respect. But it is only when we get to the region of fine arts that we find such a state of things. If we descend to sport and pastime, or the more sordid breeding of fowls, bulldogs, cattle, horses, &c., the judges for these are men who have the whole matter of points at their finger-ends. A judge of bulldogs would not probably be accepted as a capable judge of butter-making unless his knowledge was as great of the latter; that is to say, he happened to be a good judge of both. But we have judges of the pictorial whose qualifications are strictly scientific. On the other hand, we are asked to believe that painters, who know nothing of photography, will also make good Judges.

I will not discuss these matters, but will give my own opinions. I feel always that I should like my work judged by men directly in touch with me, not by painters unfamiliar with photography, nor by technical men unconscious of the pictorial. I want my work judged by men doing similar work, whose photographic aims and thoughts run in the same direction as my own; whether equals or superiors matters nought, so long as they can appreciate and understand. Let me endeavour to illustrate the matter practically. Supposing in this Society you inaugurated a competition for, say, bromide enlargements. Would you elect as judges one man well known as a micro-photographer, another renowned for chemistry, photographic and general, and a third because of his fame as a carbon worker? Would you not rather choose men whom you knew had the best experience of practically working bromide enlargements?

With a reference to the Selection Committee of the Royal Society I must bring my paper to an end. This year the Salon seems to have affected the Council of the Royal Society more than usual, for there can only be one explanation of their action in excluding the Judges from acting on the Selection Committee as of yore, viz., that some of the Judges were prominent members of the Salon. We have been told so often that the Salon does no harm to the Royal Society—indeed, that it benefits it—that it comes rather as a shock to find the Royal Society admitting the rivalry in so marked a fashion. At the same time, the Royal would not admit that their Exhibition is one whit less pictorial than the Salon, and yet they elect a Selection Committee who pre-judge the work, some members of which are not pictorial photographers. We have therefore to face this year the curious state of things of two boards of Judges, and, from the pictorial aspect, the weakest one with the most power. To my mind, there is only one thing to be done, and that is, that next year the Selection Committee must be elected, as are the Judges, by the members, and not by a small body like the Council. As this year stands, we shall not be able to judge what pictorial workers think of our work, and the awards will merely be a selection of the best of those admitted. If we are to have two sets of Judges, let them be chosen in the same manner.

WALTER D. WELFORD.

#### AMENDATIONS OF THE PLATINOTYPE PROCESS.

At the meeting of the Leeds Camera Club, on September 20, a practical demonstration and lecture on "Amendations of the Platinotype Process" were given by the president (Mr. W. J. Warren). The elementary principles of the process, said the lecturer, were generally familiar to most of them. He described the different brands of paper in the market, though what he dealt with was that of the Platinotype Company, produced under the management of Mr. Willis, the original inventor, and Mr. Warren did not think any one had ever been able to say they had received a bad tin. In the production of the paper it was absolutely necessary that it should be dried at an exact temperature, and, whilst they knew the imperative necessity of keeping it quite dry, yet it would be useful for them to know, if they did get any spoiled by damp, that they could restore it by placing it in an oven heated to the exact temperature of 100° F. In a few minutes they would hear the paper crackle, and then it would be right to use. Taking, then, the normal developer, a solution of oxalate of potash 1 part to 4 parts of water, it should not be under the temperature of 160°, and it must not be acid. The effect of acidity was to give a very black image strong in contrasts, and if not well exposed, the image would not come up. Using the same normal developer, and heating it to a temperature of 160°, a decidedly warmer and pleasing tint was obtained, the exposure in this case being rather less than usual for the cold bath. A warm brown or sepia tone was readily obtained by using the same developer, still keeping it to 160°, and adding to every ounce one drachm of a saturated solution of mercury bichloride. By doubling the dose a curious effect was sometimes obtained, the image

floating off entirely. He cautioned them against printing in the sun in very hot weather, or the same result might occur. Mr. Warren next dealt with the sepia papers, which must be developed by the special salts sold by the company, dissolving 8 ounces in 27 ounces of water; this was also heated to 160°, and beautiful tints produced. By still further heating, say, to 200°, warmer tints were obtained. It was important that the same temperature should be maintained if more than one print of the same tint was required, and he showed, by allowing the bath to cool gradually to 112°, a distinct difference in the prints developed during the time of cooling down from the 160°. He showed that the sepia bath could not be used for the ordinary papers, which clearly demonstrated that not only was the solution different, but that the salts used in the sensitising of the paper also differed, and he cautioned them against storing sepia along with the ordinary papers in the same tin. By so-called "toning" the print a variety of tints and colours was obtained. This was really a process of intensifying, inasmuch as another metal was added to the image formed, and this clings in greater quantities to that part where the greatest deposit is, and adds to the shadows in greater proportion than to the half-tones and high lights. For the uranium toning Mr. Warren gave the following formula:—

No. 1.		
Uranium nitrate .....	48 grains.	
Glacial acetic acid .....	48 "	
Water .....	1 ounce.	

No. 2.		
Potassium ferridcyanide .....	48 grains.	
Water .....	1 ounce.	

No. 3.		
Ammonium sulphocyanide .....	280 grains.	
Water .....	1 ounce.	

One drachm of each of these was added to 12½ ounces of water, the print immersed until the desired tint was obtained, then rinsed in a five per cent. solution of acetic acid.

To obtain blue, or bluish-green tints, often useful for moonlight effects:—

No. 1.		
Ammoniated iron alum .....	¼ ounce.	
Hydrochloric acid .....	¼ "	
Water .....	2½ ounces.	

No. 2 and 3 solutions as above.

Take 5 parts No. 1, 2 parts No. 2, and 5 parts No. 3, with 1000 parts of water; immerse the print till the colour appears, then wash.

#### THE BARNET WORKS.

SINCE we last paid a visit to the works of Messrs. Elliott & Son, of Barnet, many changes have taken place in the nature of the firm's business. The branches devoted to dry plates, gelatino-chloride, and bromide-paper making have advanced by leaps and bounds, and it was in order to see for ourselves the additions to the manufacturing premises which this growth in trade had rendered necessary that, on a recent morning, we made our way to the little northern town which is the centre of so much photographic activity.

The situation of Messrs. Elliott's works is an ideal one for a business which, besides being devoted to the manufacture of sensitive photographic preparations, also embraces the production of many kinds of printing and enlarging. The buildings, situated at the rear of the town on its eastern side, overlook the hills and valleys towards Essex. From the very doors of the dry-plate and paper buildings the green panorama stretches away to the hazy distance, and one might imagine oneself not merely ten miles, but ten times the distance, removed from the centre of London. The air is crisp and invigorating, and it always seems to be sunny on these northern heights.

The inclusion of a large tract of ground adjoining their old premises, and situated at the very edge of this bracing, open country, has enabled Messrs. Elliott to erect two spacious factories, each situated well away from the other buildings, so as to minimise the risk of fire and at the same time leaving plenty of space in case future extension should be decided upon. The superficial area at the firm's disposal is so great, that one of the largest photographic manufactories in Great Britain, if not in the world, might easily be erected at Barnet.

About ninety hands are employed in the dry-plate building alone. Three coating machines are used, and, at the time of our visit, no less than eighteen of the staff were engaged in minutely examining the plates as they arrived from the drying-rooms. These chambers afford facilities for stacking several thousand dozens of plates at a time. Electric light is available in this building, and we note that, throughout, the non-actinic illuminant by which the work is conducted is of the "safest" kind—indeed, in this respect Messrs. Elliott carry caution to the utmost limits. The emulsion-making and cooking-rooms are exceedingly spacious, and are furnished with the latest appliances. A large experimental

laboratory, with every imaginable convenience for chemical work, excited our admiration.

The gelatine chloride paper has a building to itself. It is coated in 3000 feet lengths, and as it passes over the coating machine it is led up to the roof by an ingenious mechanical arrangement which carries it round and round the room in festoons. When dry it is converted into a roll and attached to the cutting machine—the first of its kind we have seen at work. This instrument, as the paper passes through, acts, as it were, like a series of scissors gauged to the required distances, and cuts the paper along its length, while it travels on towards a guillotine, which then cuts it across its breadth. This machine is a most valuable labour-saver. We are informed that there are not more than three of them in use in this country.

The examination and packing of the gelatine and bromide papers is conducted with as much care and caution as if they were dry plates, so that the sensitive coatings receive the maximum amount of protection from actinic light. Indeed, in every part of these spacious works, with their many ramifications, one sees evidence of the application of a thorough technical knowledge to the production of the plates and papers for which Messrs. Elliott are so widely and favourably known. Over a hundred and fifty hands are employed at the Barnet Works. It affords an interesting idea of the growth of the manufacturing business since our last visit to realise that the whole of the rooms then devoted to the production of the dry plates could be comfortably placed inside one of the many branches of the factory which have since been erected.

The Barnet plates and papers are, we are aware, well known and appreciated over seas, Messrs. Elliott having agencies in Japan, Australia, South Africa, &c. The popularity of these productions is well deserved, for, as we have often testified from personal trial, they are of the highest quality.

The rapid manner in which Messrs. Elliott's plate and paper business has grown is an eloquent commentary on the commonly uttered opinion that photography is not so much practised as heretofore. Photography is one of the necessities of modern existence, consequently the scope for industrial enterprise which it offers is practically illimitable. Such firms as Messrs. Elliott deserve all the success they achieve.

#### PHOTOGRAPHIC COPYRIGHT UNION.

THE Annual General Meeting of the Photographic Copyright Union was held on Tuesday evening last at the Café Royal, Regent-street, W. Mr. Frank Bishop occupied the chair, and among those present were Messrs. J. Lillie Mitchell, Alfred Ellis, William Grove, Bulmer Howell (Solicitor to the Union), Hubert Elliott, E. C. Elliott, Arthur Weston, W. Downey, Horatio Nelson King, Gerald Bishop, H. Gower (Secretary), H. H. Hay Cameron, Thomas Bedding, H. Snowden Ward, E. J. Wall, A. C. Brookes, and many others.

The Chairman, in the course of a few opening remarks, said that it had been decided in future to impose an annual subscription of half a guinea on membership of the Union. The system of relying on donations, and not insisting upon subscriptions, had not been found to work well. Referring to the Copyright Bill recently introduced into the House of Lords, and in connexion with which members of the Union and other gentlemen had given evidence, Mr. Bishop said the artists who had promoted that measure were evidently suffering from swollen heads; they unduly exalted the value of paintings, and depreciated that of photographs.

Mr. Mitchell read a letter from Mr. J. J. Elliott, regretting his inability to be present at the meeting owing to absence in the United States, and warmly commending the work of the Union. Mr. Elliott thought that every photographic society should join in the work of defeating the proposed Copyright Bill.

Mr. Bulmer Howell (Solicitor to the Union), in an interesting speech, characterised the Copyright Bill as a piece of spite on the part of artists. The terms of the Bill, according to Mr. Howell, were due to Mr. Bale, of the publishing firm of Cassell & Co., and Mr. T. E. Scrutton, the former counsel of the Union, was its draughtsman. Mr. Scrutton was said by Mr. Howell to have remarked in the lobby of the House that the Bill would "make photographers sit up." Mr. Howell advised the Union not to relax its efforts to defeat the Bill on its reintroduction, and suggested that kindred societies should be invited to join the Union in its work of opposition.

On the motion of Mr. Arthur Weston, seconded by Mr. E. C. Elliott, the report of the Committee, with a slight alteration, was adopted. We append a few extracts from the report:—

"It is gratifying to find that the photographic profession generally is now much more *au courant* with the details of the Copyright Act, and more alive to the protection of their rights and the many purposes, in addition to publication, to which photographs can be applied. Your Committee strongly advises all members to continue to register their published work, and any other photographs likely to be of general interest.

"During the year the attention of the Committee has been concentrated chiefly upon the consideration of Lord Monckswell's Copyright Bill, introduced to the House of Lords during this last session, and evidence has been given before the Select Committee of the House of Lords (to whom the Bill was

referred) by Mr. Bulmer Howell (Solicitor to the Union), and by Messrs. Joseph J. Elliott, Gambier Bolton, E. Frih, and J. Lillie Mitchell as representing the Union. The Committee attended also, by special invitation, the meetings of the Royal Photographic Society and the Camera Club to discuss the provisions relating to photography in the Bill, and strenuous opposition was offered both before the Select Committee and at these meetings to the proposed position of photography from its classification in the fine-art section, which position it rightly holds in the present law under the Bill of 1862.

"Continued watchfulness will be required by your Committee and by all interested in photographic copyright in connexion with the Bill that is to be introduced into Parliament next session.

"The exceptionally heavy working expenses of the Union during the past year, on account of legal work in connexion with Lord Monckswell's Bill have been duly met, but, many members having expressed their preference for an annual fixed subscription, instead of uncertain calls for contributions for the purpose of meeting expenses connected with the working of the Union, it was thought desirable to circulate the whole of the members as to their opinion on this important subject, and so satisfactory were the large number of replies received in favour of a fixed subscription, that your Committee now advocate a return to the original half-guinea membership fee, and this recommendation appears amongst the amendments to the Rules to be proposed.

"In accordance with Rule V., which requires two members of the Committee to retire by rotation, Messrs. Frank Bishop and William Grove are the retiring members, but these gentlemen offer themselves for re-election.

"As arranged at the last General Meeting, Mr. Thomas Bedding and Mr. H. H. Cameron have audited the accounts and certify the same are correct."

After further remarks from the chair, Mr. Downey, and other gentlemen, votes of thanks were passed to the Auditors, the President, and Committee, and the meeting closed.

#### LANTERN NIGHTS AT THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

DURING the course of the Exhibition there will be displays, by means of the optical lantern, every Monday, Wednesday, and Saturday evening as follows:—

Saturday, September 30.—"A Trip to Ireland." Arranged by Mr. C. H. Oakden (President of the South London Photographic Society).

Monday, October 2.—"Flower Studies," by J. Carpenter.

Wednesday, October 4.—"Tele-photographic Studies," by E. Marriage.

Saturday, October 7.—"A Trip to Paris, *via* Newhaven, Dieppe, and Rouen," by Algernon Brooker.

Monday, October 9, "Zoological and other Animal Studies," by Henry Sandland, J.P.

Wednesday, October 11.—"Beauties Old and New in the French Riviera," by S. J. Beckett.

Saturday, October 14.—"Mountaineering within the Arctic Circle," by Mrs. Main.

Monday, October 16.—"Travels in Italy, Spain, Algeria," &c., by H. Little.

Wednesday, October 18.—"A Holiday in North Wales," by J. A. Hodges.

Saturday, October 21.—"Bits by the Way," by E. Dockree; and "Byways of Italy," by J. C. Ashton.

Monday, October 23.—"North Country Life and Scenery," by E. G. Lee.

Wednesday, October 25.—"Olla Podrida," by Tom Bright.

Saturday, October 28.—"Lowestoft and Neighbourhood," by H. Vivian Hyde.

Monday, October 30.—"Surrey Commons, Ponds, and Rivers," &c., by T. M. Brownrigg.

Wednesday, November 1.—"Animal Studies," by Chas. Reid.

Saturday, November 4.—"Belgium Revisited," by W. D. Welford.

Monday, November 6.—"Some Beauty Spots of English Scenery," by J. A. Hodges.

Wednesday, November 8.—"Palestine," by P. R. Salmon.

Saturday, November 11.—"Lucerne and its Environs," by John H. Gear.

#### THE HACKNEY EXHIBITION.

We are requested to announce that the Hackney Photographic Society will hold its Annual Exhibition on Wednesday, Thursday, and Friday, November 15, 16, and 17, 1899. The Judges are to be Messrs. Harold Baker, A. Horsley Hinton, and J. B. B. Wellington, with, as Hanging Judges, Messrs. Alexander Mackie and H. Vivian Hyde.

The following are the Classes:—Members: (A) Portraiture, Figure, and Animal Studies. (B) Architecture. (C) Landscape, Seascapes, and River Scenery. (D) Hand-camera Work. (E) Set of four Lantern Slides. Open: (F) For Pictures which have not received an award at a Public Exhibition. (G) Portraiture and Genre. (H) Champion—for Pictures which have received an award at a Public Exhibition. (I) Set of four Lantern Slides which have not received an award at a Public Exhibition. (J) Champion—Set of four Lantern Slides which have received an award at a Public Exhibition. (K) Stereoscopic—Set of four Prints or of four Transparencies.

A silver and bronze medal will be awarded in all classes except c and h, in both of which a gold and silver medal will be awarded.

A special gold medal is offered for the best picture in the Members' Classes.

A silver medal will be awarded to the best trade exhibit, or for the most useful photographic article shown by either the trade or by any amateur.

Certificates will be awarded at the Judges' discretion.

Entry forms and all particulars may be obtained of the Hon. Secretary, Mr. W. Seife, 70, Paragon-road, Hackney, N.E.

### THE STAFFORDSHIRE EXHIBITION.

The following are the awards in the Photographic Section:—

Class 1 (Champion).—1. *Wanderers from the Path*, Mr. C. F. Inston, gold medal; 2. *At Twilight*, Mr. W. E. Dalglish, silver; 3. *Fruit*, Mr. J. M. Whitehead, bronze; 4. *North Choir Aisle, Ely*, Mr. E. B. Bull, bronze.

Class 2 (Landscape).—1. *Wanderers from the Path*, Mr. C. F. Inston, silver medal; 2. *At Twilight*, Mr. W. E. Dalglish, bronze; 3. *At Littleton, Sussex*, Viscount Maitland, diploma; 4. *A Moorland Sunset*, Mr. J. T. Charters, diploma; 5. *Winter*, Mr. H. Lewis, diploma.

Class 3 (Seascape).—1. *Sunset on the Forth*, Mr. W. J. Croall, silver medal; 2. *The Breaking Storm*, Mr. C. F. Inston, bronze; 3. *A Busy Corner*, Mr. L. West, diploma; 4. *Bare of All, &c.*, Dr. J. C. Saunders, diploma.

Class 4 (Portraiture).—1. *The Workshop*, Mr. Chas. Speight, silver medal; 2. *Waiting*, Mr. J. K. H. Crawford, bronze; 3. *Portrait*, Mr. Robert Ayton, diploma; 4. *Miss Ferguson*, Mr. W. J. Byrne, diploma.

Class 5 (Architecture).—1. *North Choir Aisle, Ely*, Mr. E. B. Bull, silver medal; 2. *Choir, Salisbury*, Mr. W. Howell, bronze; 3. *Behind the Great Screen, Winchester*, Mr. C. H. Oakden, diploma; 4. *Choir Aisle at Newark Church*, Mr. A. J. Loughton, diploma; 5. *North Choir Aisle, Ely*, Mr. E. H. Lamb, diploma.

Class 6 (Ladies).—1. *A Village Worthy*, Miss E. M. Grey, silver medal; 2. *Storm, Lake of Geneva*, Miss A. Baird, bronze.

Class 7.—Withheld.

Class 8 (Instantaneous).—(Silver medal withheld) 1. *A Close Finish*, Mr. C. M. Wane, bronze medal.

Class 9 (Flowers, Fruit, &c.).—1. *Fruit*, Mr. J. M. Whitehead, silver medal; 2. *Flower Study*, Miss Annie E. Blake, bronze.

Class 10.—Withheld.

Class 11 (Enlargements).—1. *Waiting*, Mr. J. K. H. Crawford, silver medal; 2. *The Breaking Storm*, Mr. C. F. Inston, bronze; 3. *Sunset on the Forth*, Mr. W. J. Croall, diploma.

Messrs. Thomas Mottershead (Longton) and Harry Wade (Manchester) were the Judges.

### EXHIBITION AT EXETER.

The first Exhibition of needlework, photography, chip-carving and decorative painting in connexion with the University Extension Guild, took place at the Albert Memorial College, Exeter, last week. A local contemporary says that, in regard to the photographic exhibits, the work of judging was most efficiently carried out by Mr. Chas. Rowe, of Torquay, whose awards gave entire satisfaction. The section, though small, indicated some interest in the special subject—architecture—to which this portion of the Exhibition was devoted. At the same time the treatment of each subject was in nearly every instance pictorial, which was perhaps, on the whole, not an unhappy incident. An architect, or a student in architecture, might find but little to help, but the general public and the photographer, who sought for hints, would find this section full of suggestions. One worker's contributions stood out clearly from the rest, in selection and in execution. Of this work the upright print in the frame 126 was clearly the best, and to this the first prize was awarded. Two prints were included in the frame (a very unwise method at any time), and both were studies of old houses in Tudor-street. Both would be worthy of a high place in a collection of photographic survey prints, of which the Exeter Photographic Society ought to produce a considerable number before the originals have passed away, and for the sake of a record being made of interesting and picturesque portions of the city, which, in the course of time, will naturally be removed. The second prize went to No. 147, an interior of St. James's Chapel, Exeter Cathedral. This differed entirely in style from the prints already referred to, and was an example of careful detail, admirably rendered and well printed. Evidently from the same exhibitor who took the premier position came some admirable studies of the sculpture on the west front of the Exeter Cathedral. These were, in a sense, sketchy and artistic, soft in quality and of good tone. Such studies are valuable to the archaeologist and to the lover of a picture equally, and reflect the greatest credit on their producer. *Exeter Cathedral Choir looking West* (No. 121), by Miss Gidley, was an example of fine detail work, and was commended. It was printed on a very unsuitable paper, and loses quality thereby. The remainder of the section does not call for much comment, the average was fairly good. One point is emphasised here and there,

and it is the fact that amateur photographers are afraid to cut down their prints in order to get good proportions and to add to the pictorial quality. It is a pity that photographic workers do not exercise greater care and thought in mounting as to colour and to framing. Many of the prints shown could have been seen to far better advantage if these points had been considered; prints should be framed singly.

## News and Notes.

PHOTOGRAPHIC CLUB.—October 4. Mr. Henry W. Bennett, F.R.P.S., on "Architectural Photography."

MESSRS. BENDER & Co., of 242, London-road, Croydon, have been awarded two first prizes for carbon and bromide enlargements in the South German Exhibition at Stuttgart.

AN esteemed correspondent in Paris writes: "How can living pictures of the trial at Rennes be shown when even pocket cameras were not allowed in the Court House? A mystery, is it not?"

A CHEAP edition, in sixpenny weekly parts, is about to be issued of *Cassell's Gazetteer of Great Britain and Ireland*. The work is very fully illustrated from authentic photographs, and will contain sixty maps in colours. Part I will be ready on October 4.

THE West London Photographic Society will, during the forthcoming season, cater for the needs of the beginner by holding a series of six lectures and demonstrations on elementary subjects, of which full particulars will shortly be announced. These beginners' meetings will alternate with the ordinary meetings of the Society.

A NEW weekly magazine will be issued early next month by Messrs. Cassell & Co., under the title of *Sunday Chimes*. It will be very fully illustrated and will aim at supplying for the day of rest matter as high in quality and as attractive in character as that provided for the week day by their very successful publication the *New Penny Magazine*.

THE Longton and District Photographic Society's Fourth Exhibition will be held in the Sutherland Technical Institute, Stone-road, Longton, from Monday, November 20, to Saturday, November 25, 1899. The following are the Open Classes: H, Pictures previously medalled, gold, silver, and bronze medals; J, pictures not previously medalled, silver and bronze medals; K, lantern slides (sets of six), silver and bronze medals. All entries and other communications to be addressed to the Hon. Secretary, Mr. Thomas Mottershead, 43, Stafford-street, Longton, Staff.

SANDELL "PERFECT" COMPETITIONS.—The following are the results of the August competitions:—101. prize, *The Rehearsal*, Mr. Thomas Knox, Belfast; 51. prize, two studies—*The Little Artist and Tired Out*, Mr. A. Darn, Wootton-under-Edge; 11. prizes, *Lady Chapel, Bristol Cathedral*, Mr. H. E. Brightman, Bristol; *Summer*, Mr. J. M. Nisbett, Horselydown; two studies—*In Earl's Colne Church and The Drawing Slate*, Mr. C. S. Tyler, Earl's Colne; two studies—"He cometh not," she said, and *Fly catching*, Mr. W. Shaw, Camberley; *Reading and Writing*, Mr. William McLean, Belfast; *Blowing from the Nor'-West*, Mr. Charles F. Inston, Liverpool; "I've lost my way," Miss H. Phillips, Colwyn Bay; two studies—*Choir and Altar and North Side Aisle, Christchurch Abbey*, Mr. H. W. R. Child, London; *Sunshine and Shade*, Mr. E. A. Salt, South Croydon; two studies—*In Lichfield Cathedral*, Mr. Edgar R. Ball, Forest Hill.

THE Borough Polytechnic Photographic Society open their winter season on Wednesday, October 4, with a popular lantern lecture by Mr. Thomas Fall, F.R.P.S., on "Photographic Experiences." This is the first of a series of monthly lectures of a popular photographic nature, which constitutes one of the features of this Society's programme. These lectures will be held at the Polytechnic, 103, Borough-road, S.E., on the first Wednesday of each month at 8.30 p.m. and will be open to the general public at a nominal charge for admission. In addition to a strong list of Wednesday lectures and demonstrations, a connected series of practical instruction evenings has been arranged for each Friday throughout the season. These meetings are under the supervision of a member appointed for the occasion, and are specially adapted for beginners and those contemplating taking up photography as a hobby. The first of these elementary instruction evenings will be held on October 6, subject, "Apparatus: the Principle of a Lens' Action; the Functions of Single, Rapid Rectilinear, and Wide-angle Lenses." The Hon. Secretary is Mr. P. C. Cornford, 103, Borough-road, S.E.

MESSRS. FUERST BROTHERS, of 17, Philpot-lane, London, E.C., are now in a position to offer the following film subjects: *Dreyfus Trial*.—1. *Meeting of the Council of War*: The lawyers, Messrs. Demange and Labori are conversing; Colonel Jouaust informs them that the meeting is about to begin; the Court enters, and the accused is brought in; the defendants demand a hearing for General Mercier, who comes in and gives evidence. 2. *Dreyfus in his Cell*: Seated by his wife, he convinces her of his innocence, and bids her hope; a police sergeant enters, and tells Madame Dreyfus that the time for her visit has expired; husband and wife embrace one another, and Dreyfus leads his wife to the door; entrance of the two lawyers for the defence, MM. Demange and Labori; Dreyfus asks them to be seated, and they begin to examine the dossier. 3. *Entrance of the Council of War*: Dreyfus crosses the road and enters the Council Chamber; the lawyers, MM. Demange and Labori, follow, carrying on an animated conversation; then come the witnesses, General Mercier and others, also Colonel Jouaust, President of the Council. 4. *Leaving the Council Chamber*: The witnesses, led by General Mercier; then Dreyfus, accompanied by a sergeant of police, followed by his lawyers, MM. Demange and Labori. Each film is sixty-five feet in length.

**AN EXTRAORDINARY CASE.**—On Thursday, at Bedale, Sir Henry B. Pierse, Bart., remanded two travelling photographers, named Frank Johns and William Henry Hammond, until Tuesday next on a charge of obtaining 3s. by false pretences from a boy named Fred Seafie, aged fourteen, at Masham, on the 20th inst. One of the prisoners had induced the boy Seafie to have a look round their photographic booth, saying it would cost him nothing. When he got inside, they seated him in a chair and told him that, if he did not keep quiet, the place would be blown up. They then took his photograph, and charged him 3s. for four copies. The boy, being frightened, paid the money to get out, and he then complained to Inspector Holmes, who arrested Hammond in the booth. Johnson absconded, but was traced to Tansfield, where he was apprehended by Sergeant Kemp.

The Birkenhead Photographic Association will hold an International Exhibition of photographic work on Tuesday, Wednesday, Thursday, Friday, and Saturday, April 3, 4, 5, 6, and 7, 1900, in the large buildings of the Y.M.C.A., Birkenhead. The Exhibition Secretaries are Messrs. C. F. Inston, 25, South John-street, Liverpool; S. Tagg, 32, Chestnut-grove, Birkenhead; T. J. Smith, 74, Prenton-road East, Birkenhead. The following are the classes: 1. Landscape (with or without figures), one silver-gilt medal, one silver, and one bronze. 2. Seascape and Marine, one silver, one bronze. 3. Portraiture and Genre, one silver-gilt, one silver, and one bronze. 4. Architecture (exterior and interior), one silver, one bronze. 5. Photo-mechanical, one silver. 6. Photo-micrography, one silver. 7. Stereoscopic work and Transparencies, one silver. 8. Hand camera work (sets of four prints in one frame—camera must have been held in the hand), one silver-gilt, one silver, one bronze. 9. Lantern slides (sets of six) (a) Slides that have previously received an award in open competition, silver-gilt; (b) slides that have never received an award in any open competition, one silver, one bronze. One solid gold medal will be awarded to the best picture in the Exhibition (classes 5, 6, and 7 excepted). One solid gold medal will be awarded to the best set of lantern slides in the Exhibition.

## Patent News.

The following applications for Patents were made between September 11 and September 16, 1899:—

**ANIMATED PHOTOGRAPHY.**—No. 13,294. "A Method of Showing a Series of Pictures in Animation." H. WHEELER.

**NEGATIVE PAPER (STRIPPING).**—No. 18,430. "A Negative Paper to be Drawn off." Complete specification. A. HOFMANN.

**COLOURING PHOTOGRAPHS.**—No. 18,594. "An Improved Process for Producing Coloured Photographic Pictures." B. KUNY.

**DIVIDING BEAMS OF LIGHT.**—No. 18,669. "Improvements in Means for Dividing Beams of Light for Photo-chromoscopic and other Purposes." E. S. SHEPHERD.

**CAMERAS.**—No. 18,681. "Improvements in or relating to Photographic Cameras." Complete specification. W. B. THOMPSON.

**FILMS.**—No. 18,738. "Improvements in or relating to Photographic Films." O. MOH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
2.....	Camera Club.....	Opening of Exhibition of Pictures of the East, by E. R. Ashton.
2.....	South London.....	Pyro Soda Development. Ben E. Edwards.
3.....	Gospel Oak.....	Discussion: The Hand Camera, its Influence on Photography.
3.....	Hackney.....	Criticism. F. W. Gosling.
3.....	Redhill and District.....	Carbon Printing. J. O. Grant.
4.....	Croydon Camera Club.....	Short Address by the President, followed by a Demonstration.
4.....	Borough Polytechnic.....	Photographic Experiences. Thomas Fall, F.R.P.S.
4.....	Photographic Club.....	Architectural Photography. Henry W. Bennett, F.R.P.S.
5.....	Camera Club.....	Natural-colour Photography. E. Sanger Shepherd.
5.....	London and Provincial.....	Demonstration: Viol. T. Thorne Baker.
6.....	Borough Polytechnic.....	Elementary Instruction Evening: Apparatus: the Principle of a Lens' Action.
7.....	South London.....	Excursion: Chislehurst for St. Paul's Cray. Leader, W. F. Slater.

### ROYAL PHOTOGRAPHIC SOCIETY.

SEPTEMBER 26,—Technical Meeting.—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

#### APPARATUS AT THE EXHIBITION.

As usual at the first meeting of the Society after the opening of the Exhibition, the evening was devoted to the examination of the apparatus exhibited.

Messrs. G. HOUGHTON & SON'S representative explained the Sanderson Hand Camera, adapted for use in the hand or on a stand, and embodying the Sanderson universal swing front. The camera has a removable focussing screen with spring hood, a reversible back, view-finder, rack and pinion, and focussing scale, and is fitted with a Bausch & Lomb shutter working between the lenses, and giving speeds of from one second to one-hundredth of a second by hand or pneumatic release. The other exhibits of this firm were a camera, combining all the features of the Sanderson camera but at a more popular

price, and Lloyd's Rotary Trimmer, a very useful piece of apparatus in which the cutting edge is a wheel travelling along a fixed horizontal bar.

Mr. J. H. AGAR BAUGH explained the Biokam, exhibited by Messrs. John Wrench & Son, an apparatus consisting of a combined cinematograph and snap-shot camera, printer, projector, and enlarger, fitted with Voigtlander lenses for taking and projecting the pictures, and also the printing frame and developing tray for use therewith.

Mr. E. CLIFTON demonstrated the new model Dallmeyer hand camera (J. H. Dallmeyer, Ltd.), with long extension for use with lenses of the convertible type, and provided with rising and cross front, two brilliant finders, f-6 Stigmatic lens, and Bausch & Lomb Unicum shutter.

Messrs. W. WATSON & SONS' representative first explained the Gambler Bolton hand camera, designed for very rapid work and especially for studies of animals and yachts, and other long-distance work. It is fitted with a Thornton-Pickard focal-plane shutter with speed indicator, and can be used with dark slide, changing box, or roll-holder. One of its chief advantages is a full-sized finder, by means of which the image can be focused up to the moment of exposure, the pressure of a discharger causing a mirror to rise to the top of the camera and to automatically release the shutter. The apparatus, which is admirably adapted to the purposes for which it is intended to be used, has already been fully noticed in these columns. The binocular stereoscopic camera, resembling in size and appearance an ordinary field glass, was next described, its novel arrangement being that the lens is placed at the side of the instrument instead of in the front, so that the object photographed is at a right angle to the direction in which the operator is apparently looking. An accessory to this exhibit was a stereoscopic printing frame, obviating the necessity of dividing and transposing the negatives or positives. Messrs. Watson also showed the apparatus used in the Kromaz process of three-colour photography, comprising a frame containing a set of colour screens, a repeating holder for attachment to the camera and carrying the colour screens and dark slide, and a stereoscope for viewing the finished pictures. In this adaptation of the three-colour process only two pairs of negatives are taken, one pair through red and blue screens, and one pair through a green screen, and from the stereoscopic negatives so obtained positives are made, which, combined in the special chromo stereoscope, reproduce the object in its natural colours.

The TELLER CAMERA COMPANY, Ltd., exhibited the new and improved pattern of their well-known camera, which has already been noticed in these pages.

Mr. THOMAS WEBSTER showed a very ingenious book-form printing frame, designed to allow the whole of the picture to be seen at once, and adapted to printing either from plates or cut or rollable films. He also demonstrated a flashlight apparatus of extreme simplicity of construction, the magnesium powder being driven by a spring through the flame of three wax matches.

Mr. SANGER SHEPHERD exhibited a set of two-inch square trichromatic light filters for natural colour photography, adjusted for the Cadett Rapid Spectrum Plate by means of a modification of Captain Abney's colour sensitizer. He also showed examples of a simplified method of natural colour photography by trichromatic printing in transparent media, and a series of light filters for orthochromatic work on the Cadett Spectrum Plate. Mr. Cadett's Colour Sensitizer and Orthochromatic Plate Standardiser were briefly referred to by Mr. Sanger Shepherd, who also showed the spectrum plate "Safe Light."

Messrs. MARION & CO.'s exhibit included several ingenious contrivances, comprising the Massey Field and Studio Stand, a Perfect Developing Dish, Sectional Print-washer, Desk-trimmer, Soho Circular Print-trimmer, a new flat pocket-book form of the Hunter & Driffield Actinograph, a holder for supporting films during development, &c.; a tripod stay, to prevent slipping on smooth surfaces; a speed-testing printing frame, with six narrow shutters side by side for the exposure of a plate or print in strips; the Stereoscopic Swallow hand camera; and the Swallow hand camera for thirty quarter-plate cut films.

Mr. C. S. SOUTHN showed an adjustable vignetting apparatus. It consisted of two light frames of wood and metal, a lower or metal frame for attachment to the printing frame, and a top wood frame, carrying the vignetting card, capable of being raised or lowered to any angle or height by means of screwed studs and nuts and a spring.

Messrs. SPRATT BROTHERS described their long-focus light field cameras, which possess several novel and ingenious features.

Mr. J. Wheeler's metzograph screens and reticulated ruby glass were shown by his representative, and the exhibits of Messrs. J. E. Johnson & Co. (engraved screen plates), Kodak, Limited (Zenith and Kodak cameras), Messrs. Mackenzie & Co. (Daylight slide and Daylight camera), J. J. Griffin & Sons, Limited (Cyko camera and frame of curious effects with the Kachin developer), and the Secco Film Company, Limited (negatives on Secco films and prints from the same), were examined in the absence of the exhibitors.

Messrs. C. P. Goerz exhibited an apparatus capable of being used either as an opera-glass of two powers, magnifying two-and-a-half or three-and-a-half diameters, a twin-lens hand camera, or a stereoscopic hand camera, the size of the pictures being two inches by one and three-quarter inches.

#### COMING EVENTS.

October 10, Ordinary Meeting: the President will deliver his annual address, and will present the medals awarded at the Exhibition. October 17, Photo-mechanical Meeting. October 24, Technical Meetings; subjects to be announced.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 21,—Mr. R. Beckett in the chair.

The announcement of the death in Japan of Professor W. K. Burton was officially made, and it was agreed to record the deep regret which the members felt at the loss of one of the honorary members of the Association.

Mr. W. F. Slater passed round a copy of one of the groups taken in Belgium on the occasion of the recent excursion by the South London Society, in which several well-known photographers from different parts joined.

The question arose as to the arrangements for the annual outing to Hampstead in which this Association and the Photographic Club usually joined, and Mr. Freshwater was deputed to inquire as to suitable headquarters and report.

A copy of Penrose & Co.'s handsome annual was passed round by Mr. Slater for inspection. It was unanimously voted a very fine production, and was examined with much interest.

#### PHOTOGRAPHIC CLUB.

SEPTEMBER 20.—Mr. A. E. Staley in the chair.

Mr. E. W. FOXLEE, speaking upon the subject for discussion,

#### UNCORRECTED LENS WORK.

said that he had not worked much with the usual spectacle lens, but he knew and had seen much excellent work by them. He thought that in the old days such lenses were adopted much on the score of economy, and not from special appreciation of the results to be obtained. He pointed out that Steinheil's periscop was not corrected, and that it was issued with directions for adjustment. The lens used in the first Kodaks were uncorrected, but, the focus being fixed, allowance was made.

The CHAIRMAN said there were at present on the market several uncorrected lenses, and mentioned that fitted to one make of hand camera which was partly corrected—a wide-angle lens of some 120°, and cheaper than an ordinary wide-angle—Dollond's Monocle, and a German lens provided with a mechanical adjustment. Personally he was of opinion that such lenses were only used as a fad, seeing that it was now possible to obtain a whole-plate rapid rectilinear lens for 12s. 6d.

Mr. J. R. WILLIAMS, speaking of the type of camera fitted with such cheap lenses, mentioned that he knew that somebody was using a lens and camera of first class make to get specimen photographs for a 3s. 6d. hand camera.

Mr. FOXLEE said that he should also like to mention another side to the correction of a lens, *i.e.*, over-correction, and stated that Voigtlander's early Petzval lenses were all over-corrected, and that Voigtlander, while conforming to the demand for exactly corrected instruments, still adhered to the opinion that over correction was better for working. With this he agreed, and said he had bought a pair of *carte de-visite* Voigtlander lenses, which he had used for months before he found out, by testing a friend's lens on his own camera, that their foci were not identical.

**Hackney Photographic Society.**—September 19, Mr. W. Rawlings presiding.—In the course of the evening Mr. W. D. WELFORD read a paper on the subject of

#### EXHIBITIONS AND EXHIBITORS. [See page 618.]

A long and interesting discussion followed Mr. Welford's paper, in which the CHAIRMAN said that Mr. Welford had omitted to mention one advantage of exhibitions, *viz.*, that they formed good incentives for improvement. He quite agreed as to the inadvisability of competitive exhibitions, but he did not like the idea that an exhibitor should study the preferences of the particular Judges who were to judge his work. On the contrary, let each man show the best he could do and ignore the possible fancies of the Judges. On the subject of faking, he thought that a limit should be made and the line be drawn at extensive working up of the print. With the exception, perhaps, of mounting and framing, all the work should be the exhibitor's own. Mr. R. BRACKETT thought that a great improvement could be made in the judging. Judges ought to give the reason for their awards, and so make the Exhibition of much greater value both to successful and non-successful exhibitors. The system of exhibiting work only partly done by the exhibitor was a great abuse. The man who did the work ought to get the credit of it, instead of which exhibitors often got credit for work which was not their own. Concerning medals in members' classes, he thought that no friction ought to be caused by it. Mr. FARMER had known cases where Judges' decisions had caused discontent, but not in one member against another. Personally he was strongly against the practice of giving medals, and thought that the honour of having one's pictures selected for exhibition should be sufficient reward. He thought that work shown should be entirely the exhibitor's own, with the exception of framing. Messrs. W. L. BARKER and ROOFER and several other members expressed the opinion that medals encouraged many to exhibit who would not do so otherwise. Mr. HENSLEY said he would prefer to exhibit where no medals were offered. A good selection committee should be chosen and reliance be placed in it. In such a case he would consider the honour of having his picture accepted sufficient. This plan would, however, be found difficult to work in the case of a small society exhibition. Mr. FARMER thought that some refrained from exhibiting through fear that their work would not receive an award, and consequently would suffer in comparison with medalled pictures. If no medals were awarded, all would be placed on an equality, and it might be the means of inducing diffident ones to exhibit. After others had spoken, Mr. WELFORD replied. He agreed with the Chairman that an exhibition was an incentive to good work. He had advised exhibitors to study the tastes of the Judges, because he considered that there was no use in a man forcing his prints on a Judge who, he knew, would not care for them. On the subject of faking, he thought it did not matter whether the work was put on the negative or the print, or, indeed, where it was put, so long as it passed the Judges. It was a very difficult matter to draw the line as to where faking should begin or end.

#### FORTHCOMING EXHIBITIONS.

1899.

Sept. 29-Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.

Sept. 29-Nov. 11..... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.

October 11 ..... Ludlow Photographic Society. Hon. Secretary, 14, Mill-street, Ludlow.

„ 18-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.

„ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.

Nov. 27-Dec. 18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

„ 11-Jan. 1900 Huddersfield (Invitation). W. A. Beavers, Cloth Hall-street, Huddersfield.

„ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE R.P.S. EXHIBITION.

To the EDITORS.

GENTLEMEN,—I have refrained from making any reply to the numerous paragraphs respecting the Judges elected to award the medals at the R.P.S. Exhibition until our work was completed. Now, I ask you, in common fairness, to give this letter the same publicity as your attacks. You describe the Selecting Committee of last year as “a humiliating spectacle of the organizers of a rival and unfriendly Exhibition . . . having a finger in the pie of the one great representative Exhibition;” but you do not point out that there was no one present who was not a member of the Society. It is true that there were three members present who were also members of the Salon, but two were Fellows of the R.P.S. (one of these two being a member of the Council), while the third had been elected a member of the Hanging Committee by the Council itself.

Where did the humiliation come in?

You also speak of the “greatest dissatisfaction” with some of the awards of last year; yet, out of twenty-five names nominated by the members for Judges, four out of the five who acted in 1898 were re-elected for 1899, and the fifth was appointed by the Council as a member of the Selection Committee.

This year we have had a humiliating spectacle indeed! The Judges elected by the members to carry out a difficult and thankless task, have been treated by the R.P.S. and by your JOURNAL in a manner unparalleled in my experience. The Council, by a new departure, excluded the Judges from the Selection Committee. Not only was this exclusion carried out without any notice to the Judges, but this discourtesy was rendered more marked and intentional by the fact that answers to letters of inquiry from two of the Judges were withheld until a paragraph referring to the correspondence had appeared in your JOURNAL. This JOURNAL is conducted by a member of the R.P.S. Council.

This semi-official paragraph has been followed up by a series of others, which insult and bully the Judges lest the awards should not please the Editor of THE BRITISH JOURNAL, who assumes to take up a position of pharisaical impartiality.

Had I consulted my own feelings I should have at once resigned the office of Judge, but the time was too short to submit the matter to the general body of the members, and, in order to mark my sense of the treatment of the Judges, I have withdrawn from membership of the Society.—I am, yours, &c.,

HAROLD BAKER.

58, New-street, Birmingham, September 21, 1899.

#### THE STEINHEIL LENSES.

To the EDITORS.

GENTLEMEN,—I am sorry I am unable to supply Mr. Jourdain with the information he seeks. I am not a manufacturing optician, and am not acquainted with the methods of calculation followed by those who work out their lenses mathematically. But Mr. Jourdain may find much

interesting information upon this point by a study of Steinheil & Voit's work, *Grosses Handbuch der angewandten Optik*, of which, unfortunately, only the first volume was completed before Adolf Steinheil's death. Dr. E. Schröder's work, *Die Elemente der Photographischen Optik*, should also be of service.—I am, yours, &c., P. EVERITT.  
London, September 25, 1899.

## THE USE OF NETTING IN PORTRAIT PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—Seeing your remark in the JOURNAL about using a screen before the plate in taking a photograph, I thought I would send you a specimen of one I did some months ago, finishing it with the pen and Indian ink.

The screen, I must tell you, was from a piece of fine veil net, and, had I have taken a larger piece, the result would have been finer by reducing, which I think would have been an improvement in so small a photograph.

I trust the enclosed will be of some interest to you.—I am, yours, &c., D. J. SCOTT.

Camden Studio (adjoining New Theatre), Cambridge, September 25, 1899.

## OPERATORS' SALARIES IN NEW YORK.

To the Editors.

GENTLEMEN,—In reference to your column, Answers to Correspondents: "F. N." wishes to know something about operators' salaries in New York City. For first-class operators at the leading studios the principal one receives from \$30 to \$45 per week; assistants, from eighteen to twenty-five, according to ability. In the medium class of business, where one only is engaged, their salary runs from \$15 to \$25 per week. Respecting qualifications, the editor's ideas are about correct. In the first-class houses the principal operators are expected to keep well posted on the latest novelties in their line, and must be quick and obliging, and a main point is temperance. The rush of work, generally speaking, is from November 1 to about first week in January, then business falls off until about March 1, and after that date booms along until about the middle of July; then very quiet until fall again.—I am, yours, &c., T. F. PIMLOTT.

Bay State Photo Co., The Bridge, Lynn, September 23, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

LENS FOR COPYING.—A. McFEN says: "I have a whole-plate portrait lens and a whole-plate rapid rectilinear, both excellent lenses. Which would you advise me to use when copying up to the whole-plate size?"—The rapid rectilinear, because with it the field will be more evenly illuminated than with the portrait combination.

MOUNTING, &c.—R. L. E. says: "Please tell me the best paper for backing enamel, and the best mountant to use for gelatino-chloride photographs."—Any stout, hard paper will answer. A special backing paper, for the purpose, is sold by most photographic dealers. Starch paste is as good as anything as a mountant.

ADDRESS WANTED.—SOUTHPORT asks: "Could you give me the address of Messrs. Johannet et Cie., makers of drawing and tracing papers, &c., or the address of their wholesale agents in this country, if they have one?"—We are sorry we cannot supply the desired address. In all probability the paper may be had through any dealer in artists' material.

COLLOTYPE PLATES.—LITHO writes: "Can you tell me where I can buy collotype plates sensitised ready for printing from the negative? I have lithographic presses, and, if I get the plates ready-sensitised, I think I can soon be able to work the process, as I expect litho presses will answer for the purpose?"—Collotype plates are not articles of commerce. They have to be used within a few hours—or a day or two—of their preparation. A lithographic press will answer for the printing.

SALTED PAPER PRINTS, RESIDUES.—WET PLATE asks: "1. Are printing-out prints on salted paper permanent when toned and fixed like P.O.P.? 2. Will refiners buy residues containing silver, iron developer, and cyanide mixed? I know it is recommended to keep the cyanide and iron separate; but it is very difficult to do so."—1. They will be about equal in permanency, we should say—perhaps more permanent. 2. A refiner will reduce the residue for you and allow for the silver, according to its assay.

DRYING CARBON TISSUES.—S. PRIDDER says: "Kindly give me your opinion of the enclosed sketch of a cupboard I propose having made for drying carbon tissue after sensitising it. The sketch is made on a scale of about one inch to the foot."—The design for the cupboard is very good, but the sketch shows that the fumes from the burning gas would go into the closet, and they would cause the tissue to become insoluble. The fumes of the gas must not be allowed to enter the chamber.

UNEVEN TONING.—E. BALLARD writes: "Enclosed please find some collodio-chloride prints. You will see there are some streaks across them that are unequal in tone. They were kept in constant motion while they were toning, and the bath was the sulphocyanide, made according to the formula issued with the paper. Can you tell me the cause of the trouble and its remedy?"—The cause of the trouble is the unevenness in the coating of the paper. That being the case, there is no remedy for it.

DRIED ALBUMEN.—J. B. COULTER inquires: "Where shall I be able to purchase some dried albumen, which I want particularly for some experiments? I have inquired at two photographic dealers and three or four druggists, and none of them keep it. Some even told me there was no such thing."—Dried albumen may be had from such houses as Hopkins & Williams, Mawson & Swan, &c. It is also kept by some druggists, who make a feature of dyers' materials. There are two kinds, egg albumen and blood albumen, the former the more expensive of the two.

PARTNERSHIP.—NEMO says: "A and B go into partnership and take premises at J, the firm paying rent, rates and taxes. A rents part of the house from the firm A & B. The part occupied by the firm and the portion A rents from it are about equal in area. Is not the business half of premises more valuable than the private dwelling part, i.e., from a business point of view should I not the business pay the greatest share of rent, rates and taxes, &c.?"—In most cases the business portion of the premises would be worth the most; in some not. All depends upon circumstances. Such matters are usually arranged by the partners between themselves to their mutual satisfaction.

CURING HALATION.—OPERATOR says: "Kindly inform me if there is any method of removing halation after development, such as occurs in photographing interiors. I do not mean the reducing of density with ferricyanide of potassium or mechanical means. I am told, of course by an employer, that some of my predecessors have done this. The plates have been backed, and strong sunshine through the windows when the exposures were made. Under the conditions, do you think it possible to remove the halation after development? I am satisfied about the matter, but would like an answer through your JOURNAL."—Certainly, the halation can be reduced. The most general way is to rub it down with a small pledger of wash-leather moistened with alcohol.

DEVELOPING AFTER FIXING.—VARNA says: "Dr. Neuberg's experiments, 'Developing after Fixing,' THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1899, p. 980. 1. Exposure (same), 2, 6, 14, and 30 seconds (for ordinary development proper time about  $\frac{1}{2}$  second), then fixed, washed, but without drying, put into developer. Contrary to expectation, positive image began to appear in 10 to 15 minutes, and all was well out in  $\frac{1}{2}$  hour, but left film in developer over night, say 8 hours in all; then mercury chlorate bath followed by sulphate of soda. Result, as per negative enclosed: longest exposure about right; short ones, no good. Dense, however, and almost impossible to print from. Second film, 32 seconds (proper time  $\frac{1}{2}$  seconds), proceeded as before, save that part 1 was put in chlorate mercury bath about  $\frac{1}{2}$  hour after the positive image came out, and all the operations after fixing were finished within 2 hours. Part 2 was left in developer for an extra 2 hours, and then the other operations as before. Part 1 was spoiled from silver (?) spots owing to inattention, and prints so-so, but might be better with intensification. Part 2 is dense enough and to spare, and seems to have undergone partial reversal in sky at least like the longest exposed part of first film. Part 3 (not sent), of the same second film I left to dry after fixing and washing for about 5 hours, and then put it in the old developer which had served for the two first portions of the film. No image appearing after 15-18 hours, used fresh solution, when a faint trace, but with no details, came out. Have any further authoritative experiments been carried out on these lines? The process seems to offer advantages in the case of known extreme over-exposures, and for cut and roll films when they cannot be properly developed at once. Two trials are not sufficient to draw any deductions, but it would seem that very long exposures are required, at least 30 times normal; that if developed just after fixing the positive comes out quickly, and should not, after all is out, be left to lie more than 1-1 $\frac{1}{2}$  hours in the developer; that drying decreases the sensibility. 2. Metabisulphate of potash is recommended as a preservative of pyro in place of sulphate of soda, seemingly in the proportion of 1 grain of the former to 6-8 of the latter. Can the metabisulphite of potash be used indifferently with all the developers, metol, quinol, &c., or does it then work differently, as with pyro? In THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC for 1894, p. 1266, E. H. Hardy, of Sheffield, advertised (3) an 'Exposing and Developing Easel' for enlargements, &c., the exposure given and developer applied *in situ*; if exposure not sufficient, the process was repeated. The advertisement was not repeated, but I should be glad to know if the process is really practical; and, if so, whether these easels are still to be had. I cannot trust the local joints to do even so simple a thing.—1. We know nothing more of the method than was given by the author in his paper. We should recommend our correspondent to experiment further with it, as his results are interesting, and, as he says, his two trials are not sufficient upon which to form a judgment. 2. It may be used with some of the other developers as with pyro, though not so satisfactorily with all. 3. We do not know if the easel is still on the market. The thing is quite practicable, but the system is very seldom followed in this country, at least by practical workers.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The

formulae will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

OUR enterprising contemporary the *Stage* (probably the best theatrical paper published) is offering to supply its readers with an enlarged portrait copied from any photograph, and finished in black and white, size 30 x 22 inches, for the price of 12s. 6d. We have no doubt many members of the theatrical profession will take advantage of this offer. The price is somewhat low, it is true, but we congratulate our contemporary upon its honesty in refraining from the practice, only too common amongst newspapers in all parts of the country in recent times, of saying that these cheap-worked up bromide enlargements were worth "so many guineas," or that the purchaser was getting for shillings what a photographer should charge pounds for.

\* \* \*

THE Annual Meeting of the Photographic Copyright Union, which we briefly reported last week, was characterised by una-

nimity of opposition on the part of those present to the copyright Bill which was introduced to the House of Lords last session. That Bill, it will be recollected, shared the fate of many other legislative innocents and was dropped in August. We believe it is to be reintroduced next session, and we hope that it will be drafted in terms less unjust to photographers than those which distinguished the original measure, than which, we do not shrink from saying, Parliament has never been asked to sanction a greater piece of spoliation. For many years it has been said of painters that they were jealous of photography, but the remark always seemed to us as having more of the jest than earnestness in it. But, after all, how painfully true it is, for it is a handful of St. John's Wood painters, backed up by a big publishing house, which is seeking to rob the photographer of that protection in his own work which Parliament gave him thirty-seven years ago.

\* \* \*

The Copyright Union has many enemies even amongst photographers; but not one of the latter can deny that in organizing evidence in opposition to the Bill, which was considered in Select Committee of the House of Lords earlier in the year, an enormous service was rendered by the Union to the interests of British photography. That evidence was voluminous and minute; it came from the leading men of the profession, and it should go far towards convincing Lord Monckswell, who was the sponsor of the Bill, that the painters and others who are behind the measure have gone out of their way, while looking after their own interests (which, so far as we know, have not been assailed) to spitefully and unreasonably seek to injure photography. For this work the Copyright Union deserves the thanks of every photographer, amateur or professional.

\* \* \*

In all probability the Union will be called upon to maintain a defensive attitude next session, when the Bill is reintroduced. It is too much to hope or to expect that the whole of the hatred and jealousy which the painters and their publishing friends have manifested towards photography and photographers will give place to a feeling of benevolent affection during the winter months. We may safely assume that there will be more hole-and-corner meetings at St. John's Wood; a new Bill will be drafted by Mr. Scrutton, and we may be sure, to quote Mr. Bulmer Howell's last week's reference, one more effort will be made "to make photographers sit up"—in other words, if not to rob them of legislative protection for their own handiwork, at least so to whittle away or qualify the rights conferred by the Act of 1862, that what remained would be practically valueless. We have read and re-read and carefully studied those parts of Lord Monckswell's Bill which concerns itself with photographic copyright, and are of opinion that, if the Bill passed into law in its old form, it would baffle the wit of man to interpret some of its clauses, particularly that which seeks to regulate the relations of artist and photographer.

\* \* \*

HOWEVER, the Bill is dead, and no useful purpose can be served by again discussing its provisions; this we did fully and exhaustively last summer. We can only conjecture that the new Bill, whatever its intentions towards photographic copyright may be, will require watchful criticism and perhaps opposition. The work performed by the Copyright Union a

few months ago in organizing evidence will, no doubt, be continued next session. In the mean time it should be known that the Union has already been put to considerable expense in the matter, and we certainly think the time has arrived when the means for raising the funds to carry on its work should be revised. Hitherto membership of the Union has entailed no subscription; donations have come from a mere handful of supporters; the general body of photographers has contributed little or nothing. In future there is to be an annual subscription of half a guinea, and, if only to fight the painters and others who are seeking to rob photography of its legislative rights, and degrade it from its place among the fine arts to the level of bricklaying, we hope that there will be a generous response to the efforts of the Committee to make the Union self-supporting.

\* \* \*

DURING the winter we understand that steps will also be taken by the Union to organize collective opposition to the attempt of the painters and publishers to interfere with the existing law of copyright as it affects photography. That law has been found to work excellently in practice, and it makes no inroads on the rights of either painters or publishers. The whole of the photographic societies of Great Britain, numbering many thousands of photographers, amateur and professional, are to be invited to support the Union in defending the existing law of copyright from attack. We trust that the societies, when appealed to, will co-operate with the Union in this matter, so that, if a new Bill is introduced into the Lords which contains provisions unfavourable to photographic copyright, a great weight of adverse opinion will be available. Painters and publishers are already well protected by law in their respective rights, but why should productions in printers' ink and oil colour enjoy the special favour of the legislature, and photographic impressions in silver, carbon, or platinum, be specially singled out for depreciation in value, as the dropped Bill undoubtedly meant them to be?

\* \* \*

A CONTEMPORARY has a note on some experiments of Professor Spring, in preparing optically pure water. It is pointed out that such water cannot be obtained by distillation, nor by filtration, these processes having no tendency to purify water optically, but often rather the contrary. Optically pure water can be obtained by the action of a weak high-tension current on water which contains suspended matter, or by sedimentation of colloidal precipitates, such as aluminium, ferric, &c., hydroxides, or by filtration of the water through colloidal precipitates. Crystalline precipitates, such as calcium oxalate, have little or no effect, nor can organic liquids be purified by colloidal precipitation. Spring believes that the illumination of the water is probably not caused by the dust itself, but by minute bubbles, which adhere to the dust particles. These occasion different colours, in which red and orange predominate, and hence the blue colour of natural waters cannot be due to a selective absorption on the part of the suspended matter.

THE Champion Class at the forthcoming Croydon Camera Club's Exhibition not having sufficient entries to fill the allotted space, the Club has extended the date of entry until Tuesday, October 10, on or before which date all entries for

the Champion Class (gold medal) must be sent in frames to the Club rooms, 106, George-street, Croydon. Entry forms to the Hon. Secretary, Mr. W. H. Rogers, 106, Holmesdale-road, South Norwood, from whom forms and other particulars are obtainable.

\* \* \*

THE *Daily Chronicle* notes that a few weeks before the recess Sir Benjamin Stone, M.P., was busily engaged with his camera at the Houses of Parliament and the Tower of London. More recently he has turned his attention to the Guildhall, where he has been engaged for many days in photographing some of the most interesting documents bearing upon important events in English history. Sir Benjamin intends making a literal translation of the most valuable of the documents, among which are several well-known Norman charters, and the one granted by William the Conqueror to the City. After the recess Sir Benjamin intends revisiting the Guildhall and directing his attention to the librarian's department.

\* \* \*

BALLOON photography is expected to play an important part in the war that seems certain to break out between the Boers and the British. A military writer says that the captive war balloon, having taken a stationary position, eight cameras and lenses, spread round the balloon at equal distances, will enable a complete view of the surrounding country and enemy's camp to be photographed, and subsequently examined and discussed by the General commanding at leisure.

### ACETYLENE.

CONTINUOUS study is being made of the new illuminant, and to such an extent that eventually it is bound to occupy a position of the greatest importance. Meanwhile, however, the fire insurance offices continue to throw in the way of would-be users difficulties of a harassing and obstructive character. It has unfortunately happened that explosions of the gas have occurred, and naturally the companies, having no practical acquaintance with the matter, set their face against the "new-fangled" process, and will have none of it if they can so arrange. However, coal gas had to face much opposition at its first introduction, and in the present instance the natural conservatism of human nature is intensified by a fear of interference with dividends.

In the early stages of experiments with acetylene it was seen that an important factor of safety lay in the production of as pure a gas as possible, and to this end it is that so many experimentalists have been directing their attention, their various plans being the subject of mutual discussion. The impurities whose presence is hurtful fall into two divisions—those arising from impurities in the raw material, and those produced during the electric fusion. In the former category occur phosphoretted and sulphuretted hydrogen, while ammonia and cyanogen compounds would fall into the latter. Their danger lies in their liability to produce explosive compounds with the metal of the fittings or of the storage tanks, and the tendency in some cases to initiate spontaneous combustion.

With regard to the methods of purifying the acetylene by removing these injurious bodies, those most discussed recently are Luder and Cederkrutz's method improved by Dr. Wolff—the oxidation of the impurities by chloride of lime—or Frank's, consisting of the use of acid saline solutions to absorb them,

the ammonia being neutralised by the acid, the phosphoretted hydrogen absorbed, and the sulphuretted hydrogen precipitated as metallic sulphite. The use of acid saline solutions is said by Dr. Wolff to have great drawbacks; but its inventor states that it is by no means necessary to employ liquids, as the materials can be used to impregnate porous bodies such as Kieselguhr, a method suitable for a plant of small size. The latter writer points out that acid saline solutions are not, as stated, liable to cause explosions through the formation of acetylide of copper, the copper being precipitated as sulphide long before the whole of the acid is neutralised by the ammonia, even if the latter is present in large quantities (from 0.05 to 0.15 per cent. by volume being the proportion shown by a large number of experiments).

The purifying material is a very acid solution of cuprous chloride, or an acid solution of ferric chloride of known strength. One kilo of the latter suffices to purify seven to ten cubic metres of acetylene, or eighteen to twenty-five if the copper solution is used. An advantage in using the latter method is found in the fact that the copper solution can be regenerated by simple boiling and the addition of a little extra solution to make up for the copper thrown down as phosphide. Herr Christian Göttig draws the conclusion that the absorption of phosphoretted hydrogen by easily reducible metallic salts is increased by the presence of an alkaline chloride, whilst the need of using acids to prevent the formation of explosive acetylene metallic compounds is avoided.

With regard to this acetylide, the [danger of which is admitted on all hands, mention may be made of Herrn Freund and Mai's experiments. They found that, when dried at 50 to 60° C., and placed in a tube through which acetylene is passed, it explodes after a short time, but does not cause the explosion of the acetylene itself; while, before the explosiveness is developed, the acetylide must have been exposed to the action of oxygen or air while drying.

In the practical use of acetylene one grave source of danger is the after-formation of gas in the generators when the carbide has been removed from contact with the water. Dr. Wolff has measured the quantity thus generated from one kilo of carbide when, firstly, pure water was employed, and, secondly, when the carbide reservoir was over petroleum. The results were in the latter case 0.25 litres at the end of half an hour, 6 litres at the end of twenty-four hours, and 16 litres after three days, no more being then given off. In the case of water the numbers were respectively 7.25, 25, and 30 litres, but the carbide still went on decomposing at the rate of 5 to 6 litres a day. It is thus seen that great risks of explosion occur with small generators, with table lamps in particular. In large apparatus it can be avoided by the use of a sufficiently large reservoir to hold the excess of gas without undue compression. One means suggested for avoiding this constant discharge is the use of a layer of petroleum on the water, but it is open to the objection that a thin layer does not prevent evaporation of water, while with a thicker layer the probability is that it would be absorbed by the carbide, which would then be rendered impervious by water.

It will be seen from this brief account of work that the problem of safety in the use of acetylene illumination is being attacked from all sides, and there is fair ground to hope that eventually we shall have methods available which shall render the use of this most valuable illuminant as safe as the familiar coal gas.

**Lenses for an Astronomical Camera.**—It is stated in the *Scientific American*, that Mr. J. A. Brashear has just completed one of the pair of large astronomical camera doublets for the observatory of the University of Heidelberg, Germany. They are next to the largest ever made. They are sixteen inches clear aperture and eighty inches focal length. Two of these doublets, each consisting of four lenses, are to be made, and are to be used almost exclusively for the photographic discovery of asteroids. The reasons for making two cameras and objectives is to serve as a check. The track of an asteroid on an 8x10 plate is only about one-twentieth of an inch long for a three hours' exposure. As the curves of the lenses have necessarily to be very deep, the casting of the great discs was found to be very troublesome. The fund for the equipment was given by Miss Catherine Bruce, of New York.

**Igniting a Jet of Hydrogen.**—In the *Journal* of the American Chemical Society Mr. C. G. Hopkins describes a method by which a jet of recently generated hydrogen can be ignited with absolute safety and without loss of time. As soon as the action begins, collect the escaping gas in a test tube, and, when the latter is thought to be full of pure gas, remove it two or three feet from the generator and ignite the hydrogen in it; then immediately attempt to light the jet of hydrogen with the hydrogen flame contained in the test tube. If the gas is explosive, it will explode in the test tube, and leave no flame. If, on the other hand, a flame remains in the test tube with which the jet can be ignited, it is certain that the gas in the generator is no longer explosive. By adopting the precaution, therefore, of never lighting the hydrogen jet except with the hydrogen flame obtained as described above absolute safety can be ensured. Attempts may be made to ignite, the jet by this method as often as thought proper, and, if the hydrogen is properly generated, the gas will be ignited in less than a minute.

**Indecent or Classical.**—It has always been a somewhat vexed question, in proceedings under Lord Campbell's Act, as to where the "classical" ends and indecency begins, and probably ever will be. At the Southwark Police-court, one day last week, two showmen, after a remand, were committed for trial for showing studies in the nude in the cinematograph, alleged to be indecent; but Mr. Paul Taylor, the magistrate, remarked that he thought they were classical, but, at the same time, he said that the exhibition of one film, in conjunction with the language said to have been used, was indecent. As the prisoners stand committed for trial, on bail, it will be interesting to see how a jury will look upon the question? It has, if we mistake not, been decided more than once, some years ago, that a photograph of a painting of nude figures is not an indecent picture; whereas the same subject as depicted in the painting, when arranged with models, and photographed from life, was indecent. As we have just said, it had to draw the line as to where the classical ends and the indecent begins, as so much depends upon collateral circumstances.

**Cyanide of Potassium Poisoning.**—An inquest was held on Saturday on the body of a man who committed suicide by drinking a solution of cyanide of potassium. Since the cyanide has been but little used in photography, we have heard of few suicides by this poison, though the evidence showed in this case that the cyanide, a quarter of an ounce, was supplied by a chemist for alleged photographic purposes, and the poisons book was signed in the ordinary way. Photographic dealers, under the Poisons Act, are not allowed to sell cyanide of potassium, and a quarter of an ounce does not go far in photography; but we question if any photographic dealer would have supplied so small a quantity as that without having his suspicions aroused as to the purpose to which it would be applied. At the inquest it was stated that the quantity taken was sufficient to kill ten men. If it was, it was of quite a different quality from what we once got from a pharmaceutical chemist who supplied photographic materials, for we doubt if there was sufficient cyanide in a quarter of an ounce to kill one person.

**The Royal Arms Question Again.**—Last week a coal merchant was proceeded against, at the Clerkenwell Police-court, for using the Royal Arms without being entitled to do so, and was fined ten pounds, with three guineas costs. The proceedings were instituted by the Incorporated Association of Her Majesty's and other Royal Warrant-holders (Limited), "for assuming or using, in connexion with his calling, the Royal Arms, or arms so nearly resembling the same as to be calculated to lead other persons to believe that he was carrying on his business under the authority of Her Majesty, or any of the Royal family, or of any Government Department, he not having such authority." We quote the terms upon which the summons was granted in full, because, as we have said before, the law on the subject is very comprehensive, and we know that many photographers are, at present, infringing it, perhaps unwittingly. Some may not be aware that it is an offence to use, without the necessary warrant, the Arms of any of the Royal family, though we know that many do, simply on the strength that they may, at some time or other, have supplied photographs to them, and, possibly, on many occasions. However, that in no way entitles them to use their Arms, and, if they do so, they must expect, if proceeded against, to be mulcted in a heavy fine and costs. It is for this reason that we once more refer to the illegal use of the Royal Arms, though the prosecution alluded to had no connexion whatever with any one connected with photography.

**Kew Bridge.**—On former occasions we have referred to the removal of the old Kew Bridge to make room for a new one, which is sadly needed, and recommend those who wish to secure views of Strand-on-the-Green with the bridge as a background—and it forms an excellent one—to lose no time in obtaining them. We refer to the matter once more, as we read that the temporary bridge, on the other side from Strand-on-the-Green, will be open for traffic in a week or two, and the demolition of the old one will be commenced forthwith; so it will be seen that no time is to be lost by those desirous of securing pictures of this happy hunting-ground of artists, looking up the river. The old bridge has no great pictorial claims in itself, but it serves, as we have said, as an admirable background to several charming pictures. Strand-on-the-Green will, we hear, shortly lose much of its picturesqueness by "improvement" of the embankment, and the removal of several of the old cottages, which are said to be unhealthy. It may be mentioned that the best pictures of this spot, looking up the river, are to be obtained before noon or a very little after.

**Restoration of Bath Abbey.**—At a meeting, presided over by the Earl of Cork and Orrery on Friday last, it was resolved to proceed at once with the restoration of the west front of Bath Abbey, the cost of which, it is estimated by the architect, will come to something like 2000*l*. Out of that sum about 1200*l*. have already been subscribed, Lord Cork having contributed the sum of 50*l*. Up to the present we have heard of no protests by archaeologists and the like against this proceeding, such as there was in the case of the west front of Peterborough Cathedral. Outcry as there was over that, there have been no complaints after the work was completed. Repairs, in some cases rebuilding, are imperative for the stability of the structure, and photography stands as a witness as to how the original design of the architect is adhered to in these restorations. So it will do in the case of Bath Abbey, and it is to be hoped it will not be departed from. Let us have ancient buildings as they were, and their designs, whether good or bad, not "improved" upon.

#### THE NASCENT SILVER AND SUB-HALOID THEORIES.

It is easy to demonstrate, by reference to photographic literature, that most investigators of the chemistry of photography hold that the latent image formed by exposing a film containing a silver haloid to the action of light consists of a sub-haloid. Other investigators hold a different opinion, and affirm that the image consists of metallic, or so-called nascent, silver.

Professor Richard Abegg has joined the representatives of the nascent

silver theory by publishing, in the first number of the *Archiv für Wissenschaftliche Photographie*, a paper containing his views and a number of proofs which appear to him conclusive.

As these theories have been of great interest to me for a number of years, and I have also openly declared myself on the side of the sub-haloid theorists, I take the liberty to refer to the contentions raised by Abegg, and to give a number of reasons in support of my own views.

Abegg begins by asserting that, with the exception of the sub-fluoride the existence of the sub-haloids of silver has not been proved, and that those substances which are looked upon as sub-haloids should be considered as consisting rather of a mixture of normal haloid and metallic silver.

It may be pointed out, in opposition to this opinion, that, although it may perhaps be impossible to prove the existence of the sub-haloids directly, their presence must be inferred from the behaviour of an exposed film of silver bromide. It is an essential condition of the sub-haloid theory that a film of silver bromide undergoes, by exposure to light, such a change that a portion of the bromine is lost, and a sub-bromide consequently formed. If this is assumed, it must necessarily follow that, if we restore to the sub-salt the bromine which has been lost, normal bromide must be reconstituted. As silver bromide may be produced by simply adding a solution of potassium bromide to silver nitrate, let us ascertain if an exposed film of silver bromide may be reconverted to normal bromide in the same manner.

The experiment confirms the assumption. The impression formed by exposure to light disappears completely, and the image cannot possibly be developed. The same experiment was made with a wet-collodion iodide plate and a solution of potassium iodide, with the same result.

But, according to the nascent theory, the metallic silver which was present may have been converted by the haloid to normal haloid salt. In order to ascertain this, we will take a fresh-developed, fixed, and well-washed negative, which we know contains metallic silver, and immerse it in a strong solution of potassium bromide; but, instead of being converted to silver bromide, the silver, concerning which there can be no doubt, remains unchanged even after the lapse of hours. This clearly shows that there is a vast difference between the silver deposit and the product under consideration, which was obtained by the action of light upon normal bromide.

Nitric acid is a solvent of metallic silver. It should, therefore, be possible to remove the metallic silver from an exposed film, according to the nascent silver theory, by means of a dilute solution of nitric acid. This is a difficult experiment, as gelatino-bromide films cannot be used for the purpose; but the experiments of other writers have shown that this is not the case, that is to say, no silver is dissolved.

Abegg cites the fact that the impression formed by light upon an exposed film may be obliterated by means of nitric acid, as proof of the presence of metallic silver; but this evidence is discounted by the fact that many acids which are not solvents of metallic silver will destroy the impression formed by light. The changes which occur under these circumstances cannot be included within the limits of this discussion; but, under any circumstances, the action of nitric acid does not prove the correctness of the assumption of the presence of nascent silver.

It is generally admitted that the nascent silver theory starts with the assumption that nascent silver is only allied with normal haloid (we will assume normal bromide); but, in that case, how can the difference between slow and extra-rapid emulsions be explained?

According to the nascent silver theory, a very sensitive emulsion must of necessity contain a quantity of nascent silver in its original state. How is this formed? And, in that case, what change is brought about by light through its influence upon the film? Does it increase the quantity of nascent silver, and what part does the so-called normal bromide perform in the process of development? Moreover, if the plate is treated with a solution of potassium bromide before development, which does it affect, the nascent silver or the normal bromide?

A reply to these questions appears to present greater difficulties, unless we assume the sub-haloid theory, and, without interrupting the course of my argument, I will give a short answer according to the sub-haloid theory.

In this case normal bromide is only that which has been found in the presence of an excess of bromine. By contact with substances, or their solutions, which absorb bromine, it loses gradually its bromine, and changes to a sub-salt of unknown and unstable composition, and finally reaches a certain condition, in which it is reducible to metallic silver by ordinary developers.

The attainment of this definite stage of capacity for development may be brought about by divers causes, and notably by the effective action of

light. The nearer the sub-salt primarily approximates to this stage, the less work remains to be done by light, and *vice versa*. Secondly, substances which absorb bromine (sensitisers) can not only favour the formation of the intermediate stages between normal and developable bromide (ripening process of bromide emulsions, but may also bring about capacity for development, apart from light action (chemical fog).

Treatment with a solution of potassium bromide before development—even in the case of an unexposed plate—causes the sub-salt of the silver bromide to take up a fresh supply of bromine, and there is finally a reconstitution of normal bromide, or one of the intermediate stages between it and the stage at which development is possible may be brought about.

What is solarisation according to the nascent silver theory?

The sub-haloid theory asserts, if there is a greater loss of bromine than necessary to arrive at the stage of development, the sub-haloid probably absorbs oxygen as a substitute for the bromine, and oxidation occurs.

Abegg also adduces as another proof that an unexposed plate, when immersed in the developer, suffers reduction at those points where it is brought into contact with pure silver wire. According to his opinion, the metallic silver is the cause of extensive reduction, and this reduction is continuous in the vicinity of the primary nascent silver.

The frailty of this so-called proof is shown by the fact that a developable impression may be produced upon unexposed silver bromide by simply drawing the sharp corner of piece of paper across the film. Moreover, pieces of card used for the separation of films will, after the lapse of months, cause very considerable reduction. In both cases silver does not play any part, and there are many other substances that affect unexposed silver bromide films.

Abegg appears to attach great value to the following statement: "If the sub-haloid theory is carried to its logical conclusions, the activity of nascent silver must also be admitted, for, as soon as the sub-haloid, supposed to have been formed by light action, has been reduced to silver by the developer, any further strengthening of the image must be brought about by the formation of nascent silver. This strengthening of the image where the nascent silver is formed, and which takes place proportional to its quantity, is a further proof of the nascent silver theory."

This statement is difficult of comprehension. In my opinion it is merely a question of nascent silver or sub-salt, and they cannot both be maintained concurrently. According to the sub-salt theory, the sub-salt is reduced to metal, and the strength (actual density) of the negative is dependent upon the quantity of the reduced sub-salt. In no case can nascent silver, which may already be present in the film, conduce to the vigour of the image (? Ed. *Archiv für Wissenschaftliche Photographie*).

As fourth proof, Abney's experiment is cited, according to which a negative was intensified by coating it with unexposed emulsion and developing it. According to the nascent silver theory, the silver forming the negative induced a reduction of the adjacent silver bromide. But even this experiment cannot be considered conclusive, and I will return to it later. Suffice it to say, in the first place, that we are here dealing with an actual silver deposit, which is visible, whilst the nascent silver we are discussing is quite invisible. (The deposit may also be partly composed of dye-stuff, as in the case of pyro development.) We are therefore clearly dealing with a metal which has produced a developable impression where it has come in contact with the emulsion. This is nothing new or uncommon, and the experiment may easily be made with coins. It is of no importance whether it is due to chemical or electrical action, but, in either case, developable sub-bromide may be formed.

Another experiment of Abney's is also adduced, in which a film of unexposed emulsion is coated upon an exposed film. The image obtained by development was stronger in the upper than in the lower film.

Abegg concludes from this that reduction proceeds from the nascent silver situate at the contact of both films, and spreads in proportion to the activity of the developer. The image in the upper film must therefore be stronger, because it is attacked without any loss of power by the fresh developer. If both films are separated by a layer of pure gelatine, no image is formed, because "the nascent silver cannot exercise its function owing to this layer."

This fact, which is adduced as one of importance for the nascent silver theory, is very generally understood, and known as "transference of the image. In Liesegang's *Almanach* for 1883 we find the caution, "After exposure, the plates must not be placed in contact with each other, as the image transfers itself from one plate to the other." This, of course, is only the case when the plates are placed film to film, and I once had the opportunity of seeing an image which had been thus transferred; but the phenomenon is of much rarer occurrence than usually supposed.

The explanation of this, according to the sub-salt theory, is as follows: When a film deficient in bromine is placed in intimate contact with another film rich in bromine (which is certainly the case when an exposed plate is coated with emulsion), a struggle is set up to establish an equilibrium, and the film deficient in bromine robs the richer film by diffusion. In this manner an action equivalent to exposure is set up in the unexposed film. The impression formed by light upon the exposed plate is reduced in a corresponding manner. If the action is sufficiently prolonged, both films will develop similarly.

The following experiment of Abney's teaches us unquestionably that this process actually occurs. Cyanine is sensitive to light, and it is decomposed by yellow light. If a glass plate is coated with *platin collodion*, stained with cyanine blue, exposed to the spectrum, then coated with silver bromide emulsion, and developed *without fresh exposure*, an image is obtained upon that part which was exposed to the yellow rays, and where cyanine blue shows a band of absorption. This is easily explained by the sub-salt theory, but what explanation does the nascent silver theory offer as to the production of this image?

If we assume that decomposed cyanine absorbs bromine, the formation of the image is precisely the same as in the above case of transference; but, by the nascent silver theory, the formation of such an image is impossible, because no nascent silver can have been formed, and be it noted that the image is only formed where the cyanine has been decomposed.

Referring to the ripening of emulsions, Abegg attributes this to the formation of a certain quantity of nascent silver, and will not admit a modification of the silver bromide. "There should be little nascent silver in slow, but a considerable quantity in very rapid, plates, and adjacent thereto only normal bromide, which has not been affected by the ripening process."

According to the theory, nascent silver is the cause of development. In the absence of any explanation of the peculiar action of nascent silver, we should expect that its presence in large quantity should be conducive to more even reduction, and therefore to finer grain, whilst only a small quantity should cause uneven reduction and coarser grain. But this is in flat contradiction of facts, for very rapid plates (rich in nascent silver) are coarse, whilst very slow plates (poor in nascent silver) are fine in the grain.

In conclusion, reference is made to the development of bromide plates fixed immediately after exposure. Abegg arrives at the very remarkable conclusion that the difference between chemical and physical development is purely superficial, for he says: "In both cases the reducing constituent of the developer produces finely divided metallic silver. This takes place either from the silver salt contained in the film, or that which is added to the developing solution, and the nascent silver, by its attraction, requires most deposit where its presence is most abundant."

According to this, in the silver bromide dry process, the developer forms metallic silver from silver bromide (N.B., normal bromide, consequently also from the unexposed parts), and this wanders to the parts where most nascent silver is present, and there deposits itself permanently. According to the nascent silver theory, this migration of metallic silver must take place within the gelatine film, although it may be very circumscribed, if not quite impossible, for in those parts where nascent silver has been formed in largest quantity by the action of light, least metallic silver can be reduced, although most is required. It must here be distinctly observed that, in the physical development of a wet plate, the metallic silver image is formed by the developer almost exclusively upon the surface of the sensitive film. The metallic silver deposited from the silver nitrate possesses a freedom of mobility quite different from that which appears possible in a gelatine film.

However, it is unnecessary that there should be any "wandering" or "deposition" of metallic silver formed by the developer. But it must be admitted unconditionally that metallic silver can only be formed from silver bromide through the action of light, and this must remain precisely where it was formed. Deposition upon nascent silver is therefore superfluous.

But, if we adopt the conclusion of the nascent silver theory, that the nascent silver reduces the adjacent silver bromide, it follows that, in the wet-plate process, there should be a general reduction of the film, and, conversely, it should be easier to develop a dry plate physically, which appears to be a *desideratum*.

It is difficult to ascertain how the formation of the image (imperfect, by the way) is really effected in the Kogelmann experiment (development after fixation), but, according to my opinion, it is far from proved that this is due to nascent silver.

Our knowledge of the process of fixation is still very obscure, as shown

by the fact that the most perfectly fixed albumen print may yellow in the high lights by formation of silver sulphide, from which it follows that a solution of hyposulphite of soda leaves an undestroyed silver compound behind, the nature of which is unknown. It is therefore equally possible that a compound may be left in the gelatine by the sub-salt, instead of the assumed nascent silver.

Moreover, as nascent silver is regarded as metallic silver, but cannot be seen with the naked eye, its existence appears more doubtful, from the fact that hyposulphite of silver has the power to dissolve silver to some extent. This is exhibited in a marked degree in the printing processes, where the visible metallic deposit (products of reduction) obtained by the prolonged action of light upon salts of silver is largely dissolved. Even the metallic deposit of a normally developed negative is largely dissolved under atmospheric influences. It seems very problematic, under such circumstances, that fine, invisible, nascent metallic silver should not be attacked and destroyed.

If nascent silver is identical with metallic silver, then it must behave in the same way, and this gives rise to numerous consequences. How can Abney's cyanine experiment be then explained? But, if the so-called nascent silver is not metallic silver, what remains but the inference of a sub-salt?

As long as no more conclusive grounds are offered for the existence of nascent silver, I shall maintain that the sub-salt theory is more simple and reliable than the nascent silver theory. G. MEERCATOR.

#### IS THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION REPRESENTATIVE OF PHOTOGRAPHY IN PRACTICE?

A FOREIGNER visiting the Pall Mall Exhibition might possibly imagine that he would find it representative of the processes most generally worked in this country. If he did, he would certainly find himself considerably misled. Taking the 368 frames as given in the catalogue, we find that, where the processes by which the photographs were made are mentioned, two-thirds of them are by the platinotype and carbon processes, while there are only five by the gelatino-chloride process. There is only one mentioned print on albumen paper, and one "developed silver" print. Now, our benighted foreigner might well imagine that two-thirds of the photographs produced here were either platinotypes or carbon pictures, and that albumenised paper had become extinct; also, as there are no collodio-chloride pictures shown, that this beautiful process was quite unknown here. Now, as a matter of fact, by far—very far—the larger proportion of the work produced by professional photographers and the majority of amateurs is either P.O.P. or albumen paper, collodio-chloride coming in for its fair share. The two processes that figure so largely in the Exhibition are, as compared with the three last-named processes, but little used in every-day practice. Again, collotype printing, by which hundreds of thousands of prints are turned out annually, if not weekly, in this country, does not find a single place at Pall Mall; neither does process work, which at the present time is perhaps the most important branch of commercial photography, and has made more important strides during the past few years than any other. Yet there is supposed to be a technical section of the Exhibition.

#### FOREIGN NEWS AND NOTES.

**Blue Prints and Photo-zincography.**—C. Fleck, writing in the *Photographische Chronik* on the use of grained zinc plates for three-colour printing, gives the following formula for preparing a ferro-prussiate sensitising solution. The prints produced upon the zinc plates are only used as a guide by the artist, who makes three-colour drawings as in chromo-lithography. For the sensitising solution take—

Distilled water .....	100 c. c.
Alcohol .....	15 "
Ammonio-citrate of iron .....	15 grammes.
Ferricyanide of potassium .....	10 "
Gum arabic .....	5 "
Honey, or caramel .....	2 "

The gum arabic may be replaced by three times the quantity of albumen, or five times the quantity of fish glue. The plates should be immersed, before coating, in dilute filtered gum water, and to obtain an even film the plate should be twice coated with the sensitiser, starting each time from opposite corners. Equalise the film upon the whirler, and dry over a spirit lamp. Print till the shadows

are slightly bronzed. The printing must be done in sun or electric light. If over-printed, reduce with yellow prussiate of potash. The correctly exposed prints should be washed for ten minutes in water, and the image thus obtained is in Prussian blue. After drying, the drawing may be made over the print with Lemerrier's chalk, No. 2.

**Printing-out Paper.**—In the *Bulletin de la Société Française* M. A. Blanc gives the following directions for making gelatino-citrate paper. The name, although in general use, is somewhat misleading, as most of the papers contain very little citrate of silver. The sensitive salt is mostly tartrate, and the chief characteristics of the paper are due to it, viz., fine blacks and whites, and facility of toning. The defect of citrate papers is their want of keeping quality, but this is obviated by use of a preservative solution consisting of—

Alcohol, 90% . . . . .	15 c. c.
Pale orange shellac . . . . .	5 grammes.

Dissolve by heat and rapidly pour into 100 c. c. of boiling water, filter through cotton-wool. The emulsion thus formed will keep for a considerable time.

To prepare the citrate emulsion take—

A.	
Gelatine . . . . .	9 grammes.
Chloride of cobalt, 5% solution . . . . .	6 c. c.
Neutral tartrate of ammonium . . . . .	2 grammes.
Citrate of ammonium . . . . .	$\frac{1}{2}$ gramme.
Water . . . . .	70 c. c.

Mix the above in a porcelain [coffeepot of about 150 c. c. capacity, and then dissolve in a smaller vessel.

B.	
Citric acid . . . . .	2.3 grammes.
Distilled water . . . . .	20 c. c.

To this solution add 2.5 grammes of crystallised nitrate of silver. Place both vessels in a water bath and keep the temperature between 70 to 80° C., not above. After well mixing, pour B into A quickly and at once, well stir and add—

Alcohol, 90% . . . . .	10 c. c.
Preservative emulsion . . . . .	5 "

Mix again and filter through cotton-wool.

The emulsion is at its best as soon as made, and is still good the next day, but afterwards it rapidly deteriorates. The coated paper, however, is of excellent keeping quality.

M. Blanc makes the following comments concerning the emulsion:—

1. The alcohol facilitates coating on account of the viscosity it imparts to the emulsion.
2. The chloride of silver is the principal sensitising agent.
3. The pluckiness of the image is due to the tartrate of silver.
4. The citrate of silver has a moderating effect.
5. The citric acid, in sufficient quantity, accentuates the contrast between the lights and shadows. It plays an important part in conjunction with the shellac in preserving the paper.
6. The free nitrate of silver gives depth to the image. An excess would be useless, and less than the given quantity would lead to inferior results.
7. Glycerine should never be added to the emulsion, as it detracts from the toning quality.
8. The emulsion should not be washed. Even if slightly, the quality would be lost.
9. Albumen, tartaric acid, sugar of milk, ammonia, and other substances have been used by the author, and have been found either useless or detrimental.

**To Preserve Fish Glue for Process Work.**—Herr Gaedicke recommends the following method in the *Photographisches Wochenblatt*. Clear the whites of some fresh hens' eggs and beat them to froth. Let them settle for twelve hours and pour off the clear fluid. The following stock solution should then be made up:—

Albumen . . . . .	7 c. c.
Fish glue . . . . .	7 "
Distilled water . . . . .	14 "
Carbolic acid (five per cent.) . . . . .	1 "

After well mixing, filter the solution thrice through cotton-wool. The solution will become perfectly clear if it is allowed to stand for

some weeks; but this is unnecessary, as the particles which produce the cloudiness are so fine that they may be disregarded. A ten per cent. solution of ammonium bichromate should also be prepared. Both solutions are stable. For use mix four parts of fish-glue solution with one or two parts of bichromate solution, and then add ammonia drop by drop until the fluid is of a greenish-straw colour. The sensitised solution should be mixed fresh each day, and the unused portion thrown away. This method will be found conducive to regularity and certainty of results.

**To Steel Copper Plates.**—Herr Gaedicke also recommends a bath composed of—

Water . . . . .	4 litres,
Sulphate of iron . . . . .	1 kilogramme,
Chloride of ammonium . . . . .	1 "

for galvanising copper plates and coating them with "steel." The solution should be acidified with sulphuric acid, to prevent the deposition of basic iron oxide. It was thought that photogravure plates might suffer from loss of detail if coated with "steel," but in practice this fear has been proved to be groundless. The life of a plate is enormously lengthened by the process, and the two-thousandth copy has been found very little inferior to the first.

**Platinum Toning.**—Under the heading of "Printing Processes," Professor Valenta contributes a paper to the *Archiv für Wissenschaftliche Photographie*, and in it refers to his experiments with various amines in the preparation of toning baths. Very favourable results were obtained with m-phenyl-endiamine, the formula for which is

It is obtained by reduction from m-dinitro-benzole with tin and hydrochloric acid. Although this substance decomposes solutions of gold chloride very quickly, which renders it useless for gold toning, it acts very slowly upon the salts of platinum. A very suitable platinum bath for toning matt papers may be prepared with it, and Brandt & Wilde's Anchor matt celloidine paper has given excellent results. Professor Valenta recommends the following formula:—

Water . . . . .	100 parts.
Potassium chloro-platinite solution (1:100) . . . . .	10 "
M-phenyl-endiamine solution (1:100) . . . . .	10 "

The prints should be vigorous and washed slightly before immersion in the bath. Fix with ten per cent. hypo solution, and wash in running water. The tone is an intense black with pure white. If blue-black tones are wanted, the prints, after the first washing, should be slightly toned with a borax bath (water, 100 c. c.; borax, 10 grammes; fused acetate of soda, 10 grammes; chloride of gold solution, 40 c. c.). They should then be well washed and toned with the platinum bath. The whites will suffer if the prints are insufficiently washed between the two toning baths.

#### SOME PHOTOGRAPHIC COMPARISONS.

At the meeting of the Leeds Camera Club on Wednesday, September 27, the President (Mr. W. J. Warren) in the chair, there was a large attendance of the members and their friends to hear Mr. A. Horsley Hinton, editor of the *Amateur Photographer*, give a lecture on "Some Photographic Comparisons."

At the outset Mr. Horsley Hinton expressed the pleasure it gave him to see his Yorkshire friends so well represented at the large exhibitions just opened in London, and also that a member of their own Club had been awarded that much-coveted distinction, the Royal Photographic Society's medal, and, though he did not infer that acceptance at the London exhibitions was the only thing to strive for, yet, as things were at present, a medal at one and acceptance at the other are the two highest recognitions of merit which the world can bestow upon photographers, and he hoped that in the future Yorkshire photographers thus distinguished may increase. It might be a useful comparison to endeavour to trace why there should be amongst them some dozen or so who were so much better than their fellows, and they would find it was due to hard, trying persistence and self-devotion. Too many of them did not approach it in the right spirit, but made it more of a pastime, and it was often a question as to whether they should take their camera, their dog, or go to a football match. Each photographic excursion should be a continuation of the previous one, the interval being occupied by thought and consideration, based on the experience which the previous

outing had given. He did not suggest they should make it a serious business, and the only pursuit outside of their daily avocation, but rather to suggest that what they did do they should do well, and on the right lines. They obtained at their lectures the best instruction and advice, and those who did succeed were those who made their hobby continuous and persistent. He did not ask them to spend whole days dreaming away in the fields, but they would find it better to spend an afternoon in studying, watching, and familiarising themselves with the various moods of nature in any given district, without even troubling to expose a plate, and then going again, with the full recollection of their previous impressions, would give them a sympathy with their subject which no other course would obtain. The lecturer next dealt with the manipulations of the negative, and, by comparison of the prints taken direct from the negative, he showed how, by a judicious system of printing and the subordination of certain parts, the lighting of others, how the harsh, matter-of-fact print, devoid of all feeling and utterly untrue to nature, could be transformed into a picture full of life and feeling, conveying to the mind those impressions of nature which the worker felt when he made the exposure. The photographic camera will, said Mr. Hinton, play you many tricks. It will make the blue sky come out white, the grey-green foliage of the willow trees as dark as the Scotch fir or the cypress, show distance and rich shadows harsh and solid, and in a thousand other ways play you false unless you have studied, watched, thought over things, and become intimately acquainted and accustomed to nature. You will then, perhaps, discover that the phases which impress you most, and the memory of which it is most easy to carry, are those when clouds lour, and the low light throws long slanting shadows, and the moisture-laden air suffuses all with delicate grey mists.

The lecture was followed with the closest attention, and a very cordial vote of thanks was tendered to Mr. Horsley Hinton for his remarks and beautiful examples of some of his finest work, shown by way of illustration, much of which was from negatives obtained in Yorkshire.

#### LIGHTING: ITS IMPORTANCE IN PHOTOGRAPHY.

PERHAPS there is no more important factor in the obtaining of successful results by means of photography than the possession of a thorough knowledge of the most suitable form of lighting to employ in the particular class of subject being dealt with.

It does not matter what particular branch of photography is being pursued, *lighting* is of the utmost importance, and any negligence in regard to it is certain to be reflected in the quality of the work turned out.

In portraiture, for instance, any one who has never experienced the difficulty can form no idea of the amount of labour and thought that is incurred in the fitting up of a studio before the best effects in lighting are obtainable, and, if this be necessary for the production of not only portraiture where specially fitted-up studios are concerned, but what is of equal importance, lifelike results, how much more difficult is it to obtain anything like equal results in what is termed "home portraiture," a branch of photography now largely practised by thousands of amateur workers, who derive a large amount of pleasure therefrom.

In studying any face it is intended to photograph, the first aim should be to ascertain what light best suits it, and it only requires but a little consideration by any one desirous of practising portraiture to understand that the light most suitable for one face would not by any means be equally so for another.

Therefore it follows that the professional, working in a specially fitted-up studio, has at command, by means of his top and side lights, each of which is furnished with a well-devised system of screening, a power which enables him to execute portraiture in a manner superior to that which any one working without these adjuncts and facilities need never expect to attain; and, if we examine still further into the question of what is required in lighting a face to its best advantage, we will find that not only must consideration be bestowed upon the amount of direct and diffused light employed, but some thought must be given to the proper direction from which both the direct main and also the diffused lights are permitted to fall on the face and figure of the sitter.

Portrait painters, as a rule, work with a side light falling at an angle of 45°, because this is found to suit the majority of faces; and this has been followed in a great measure by professionals in the construction of their studios.

In executing portraiture outside a specially fitted-up studio, say, in such a situation as a large-sized room having an ordinary window, much may be done to assist and improve the lighting of a face by means of a few well-arranged screens and reflectors.

When work of this kind is attempted in an ordinary room without any such provision being made, it generally ends in failure, by reason of the lighting showing too powerful contrasts, and this is painfully evident by the shadow side of the face coming out almost black, whilst the side next the light is far too hard—results brought about by a want of diffused light, to obviate which not only must there be provision made to throw reflected light upon the shadow side of the face, but, what is of much greater importance, the light that is permitted to reach the

side of the face next the window must be filtered or diffused by means of thin transparent muslin screens.

In carrying out an arrangement of this kind it does not necessarily follow that the entire surface of the window should have blinds fitted to it, for this would tend to cut off an amount of useful light, that can ill be spared when working under such cramped conditions of lighting. All that is required is to provide some simple screen of muslin of just sufficient dimensions as will be capable of diffusing all the main light that otherwise would reach the face. A screen of muslin, made by stretching this material on a light frame three feet square, so that the frame can be interposed between the face and the window at a point just outside the range of the lens, will be found to work admirably.

Any one desirous of attempting portraiture in ordinary sitting-rooms would do well to try the following experiments, from which he will be able at once to judge of the immense importance that is attached to the proper lighting of the face. At a distance of, say, four feet from any ordinary window, let a sitter be placed on as low a chair as possible, and let the body be posed so as to have the chest and front part of the figure almost facing the window, but not quite under the full light of same; then, without moving the chest or figure, let the face be turned away from the window until a somewhat side light only falls upon it. If the operator now steps back and views the effect of such a disposition of lighting, he will at once see that it is quite unsuitable, for the side next the window is much too brightly lighted, whilst the off-side of the face is enveloped in deep shadow, in which the finer details of the face are entirely buried. At this stage let the operator bring to his aid the services of some kind friend, and, without altering the position of the sitter or moving from the same spot from where he viewed the effect, let his friend or assistant hold up slightly above the head of the sitter, at a point between the same and the window, the muslin screen described previously, and the very moment it is placed in position he will be surprised at the change that comes over the sitter's face, for not only will the side next the window, that was previously far too bright, appear to be beautifully softened down, but the shadow side will immediately appear to lighten up, and the dense shadows previously apparent will disappear, and detail spring into view that was entirely unseen before the screen was placed in position. And, if at this stage the services of some simple reflector be brought into requisition, so that a somewhat front side light be thrown upon the front as well as the shadow side of the face, a marked improvement will have been effected, and, under such conditions, heads and busts may be well photographed in any well-lighted sitting-room; but it must not be imagined that full effect is capable of being given to every class of face in such situations, for this is really impossible with some kind of faces, where more or less top light is required to yield lifelike results, and which can only be attained in properly fitted-up studios.

In another branch of photography, viz., copying, lighting also plays a most important part. Take, for instance, the photographing of oil paintings. Here, again, we see the need of having command over the light that is permitted to reach the object, for hardly any two pictures will be found that require exactly the same treatment, as, apart from the ever-varying range of colours met with, there are also great differences in the skies, some paintings having wide expanses of such and others none at all, and these large portions of what may be termed high lights in a painting require to be specially treated in the way of lighting, otherwise these parts are hopelessly over-exposed before the details in the darker portions are sufficiently brought out, and it is only by unwearied practice that any one becomes expert in the copying of oil paintings. That very much of the success in this work lies in being able to have complete control over the light at command the writer well knows, for his experience, gained by photographing hundreds of oil paintings during recent years, has clearly shown that there is a best form of lighting for this particular class of work, and this will probably be found by those anxious to undertake the work in the direction of a top light alone; but it must also be a very high light, and the studio must also have plenty of length, so situated that sunlight never reaches it. With such a high top light there is no difficulty experienced with reflections from the surface of the paintings, provided they are placed upon the easel in a vertical position and suitable material is spread over the floor. This is the natural outcome of a simple law in optics, and without a suitable light there will be no end of trouble in equally lighting the surface of any picture, and, in the case of oil paintings, any broad expanse of reflection is quite fatal.

The obtaining in monochrome of correct colour values when photographing coloured objects is quite a different matter now to what it was fifteen years ago. At that time the reproduction in monochrome of coloured objects was considered well-nigh an impossibility, and what was attempted in this direction before the introduction of chromatic plates was confined chiefly to the manipulation of the negative and the special treatment of same in printing.

These negatives were generally produced in a thin, fully exposed form, and were largely worked up by hand, such as the strengthening of high lights and half-tones, and also giving depth to the shadows, thereby lowering the tone of the colours which came out too prominently and raising others to their proper proportions. Although in the copying of oil paintings more or less of this kind of modelling is still practised, the

wonderful improvements effected in the orthochromatising of plates has tended to reduce the labour previously necessary to a very great extent, and now, with a well-appointed system of top lighting and facilities for shielding certain portions of the object, results are obtained far in advance of those produced years ago.

In connexion with the photographing of numerous light-coloured objects, such, for instance, as statuary, the direction of the main light, as well as the quality of the light employed, plays a most important part if pleasing results in light and shade are to be secured. It is quite surprising the difference in appearance such objects will present under varying dispositions of light.

With heavy objects, such as statuary, much difficulty is sometimes experienced when they have to be photographed in unsuitable positions. As a rule, however, a well-diffused top light, backed up with, when necessary, an increase of reflected light at such points as bring into strong relief such parts as require to be portrayed as high lights, will be found to yield excellent results.

Heavy statuary as a rule, especially in all well-appointed public galleries, is never placed in a situation without a considerable amount of thought being bestowed upon the manner in which it is to be lighted, but it will be found very often the ever-varying direction of the sunlight and daylight always yields a particular hour of the day when it is seen to the best advantage, and this should be closely studied when photographing same.

In commercial work there are innumerable instances where special provision has to be made for certain objects, among which may be mentioned such articles as delicately formed fabrics, in which fine tracteries are present, and in which also the design is represented by the form of the fabric, an instance of which we see in lace articles and fine embroideries. When dealing with many of these, special provision must be made when stretching them, so that the design of the lace is not interfered with by excessive stretching, and this is best accomplished by using a special stretching frame, which only applies equal tension in all directions. Lace curtains, for instance, have frequently to be photographed for process-work. Here, again, not only must special attention be given to the lighting, but they must be treated in such a manner as to bring out the pattern and design in bold relief. This is accomplished by photographing them when they are suitably distended on stretchers, and placed under a very high top light only, with an absolutely black background, and this must on no account be brought close up to the fabric, as many suppose, and sometimes actually place in contact with the curtains.

For a background in work of this description there is nothing to equal black velvet, placed at least twelve to fifteen inches behind the fabric, and when such arrangements are carried out, and a slow transparency plate used with a very full exposure under a high top light, beautiful reproductions of the finest design and tracteries are possible of accomplishment.

In work of this description the faintest inequality in the lighting will be apparent when the negatives reach the printing stage, so that it frequently happens that some experience and previous test of which is the best portion of the studio to employ at a given hour of the day is required, so as to produce nice even results that permit of good process blocks being produced.

T. N. ARMSTRONG.

## ALUMINIUM.

ALUMINIUM, which was among the many discoveries of the great Sir Humphrey Davy, is the lightest metal manufactured, and is consequently largely used at present for optical, mathematical, and scientific instruments, several purposes in photography, bicycles, ship-building, and has also been tried for cooking utensils. Although possessing many advantages over other metals, it has some disadvantages; if some of these disadvantages can be overcome in the future, the metal will be very extensively used. Its advantages are lightness, strength, almost absolute freedom from oxidation by the atmosphere, the ability to take and keep a highly polished surface, almost like silver in appearance; it is not attacked by nitric or sulphuric acids at ordinary temperatures, but will dissolve in hot sulphuric acid and in hydrochloric acid at ordinary temperatures. The disadvantages are that it is attacked by all alkalies, will not solder well, is rather difficult to work, and does not stand friction well.

Taking its advantages first, articles manufactured from it are about one-third the weight of those made from brass, copper, gun metal, or nickel silver; and, especially in surveying instruments, which often run rather heavy, and sometimes require to be carried about a good deal, the saving of several pounds' weight is a great consideration in a long day's work, the strength of aluminium is surprising, almost equalling that of steel, and for many purposes its freedom from oxidation by the atmosphere, and the fact that it is not affected by most acids, is a great consideration.

Turning to its disadvantages, its liability to be attacked by all alkalies is greatly against it being used for many purposes, as no aluminium article should be used for solutions of any of the salts of calcium, strontium, barium, lithium, sodium, potassium, and ammonium, as the alkali

solution brings up what appear like little blisters upon the aluminium, and turns it black. This has been very much overlooked by manufacturers, or we should not see cooking utensils made of aluminium, although in a good many ways it is very suitable for such purposes, for it is a good conductor of heat, thus economising fuel. Its lightness is a great advantage for large vessels. It is not affected by the acids in food, consequently no injurious metallic compound finds its way into the food; but, on the other hand, cooking utensils almost invariably have to contain, or be cleaned by, some solution of sodium, either in the form of the chloride or common salt, or the carbonate commonly known as washing soda. This fact also debars it from serviceable use in ship-building, for which purpose, on account of its strength and lightness, it seems especially fitted; but, sea water being highly charged with chloride of sodium, attacks aluminium very quickly. In proof of this, an interesting experiment may be tried. If a fairly strong solution of soda or potash is heated to well over 100° F., but not allowed to boil, and a piece of aluminium is immersed in the solution, all round where the aluminium is, the water will appear to boil. On taking the aluminium out, the water is found to be quite still again; but, on reimmersing the aluminium, the effect is reproduced. The stronger the solution of the alkali, and the higher the temperature of the water, the more quickly does the action take place. If the solution is only faintly alkaline, the effect is so slight as to be scarcely noticeable. The explanation of this phenomenon is that the aluminium has the property of decomposing the water into its elements, and of being itself dissolved by the soda or potash, forming aluminium hydrate.

Formerly aluminium was very expensive, as sodium (also a very expensive metal) was necessary to extract it from the clay from which it was obtained; but the increased demand for it, and the improved methods of production, have gradually reduced the price, and it is now one of the cheapest, as well as one of the most plentiful, of metals, and, by reason of its lightness, one pound goes as far as three pounds of brass or other metals, thus reducing it to one-third of its cost price as compared with other metals; but the difficulty in casting and working it tends to make articles manufactured from it expensive, or, at any rate, more expensive than those from other metals. Aluminium castings require to be carefully made, or they are liable to be spongy and useless.

Although aluminium may be turned very well in a dry state, some lubricant (generally turpentine, or turpentine mixed with paraffin) is necessary for filing, drilling, tapping, planing, &c., or the metal tears and scratches, and no smooth or satisfactory surface can be obtained. Another difficulty is that no suitable and reliable way has yet been found of soldering aluminium, so that parts which require to be joined must either be screwed or riveted, this being more expensive than, and not so satisfactory as, soldering. This opens out a good field for inventors, as, undoubtedly, a good aluminium solder, or flux, would have an extensive sale. Aluminium is found in rubies, sapphires, topaz, corundum, diaspore, granite, basalt, porphyry, felspar, emery, clay, and the useful family of alums, aluminium being the element which makes the latter such a valuable mordant in dyeing, as, in conjunction with many of the dye colours, it forms what are known as lakes, which fasten on to the fibre of the material that is being dyed and make the colour fast. Aluminium is also the element which mainly helps to make alum so largely used by photographers and process workers for hardening gelatine, to which it also acts as an antiseptic.

Aluminium can be alloyed with most metals, but does not form an amalgam with mercury. Four to ten per cent. added to brass or copper greatly increases the strength of the resulting bronzes, they then being able to stand about three times the strain that ordinary brass or copper will.

If two aluminium surfaces are allowed to work together, the friction causes them to what is technically known as "fret," i.e., they wear out quickly, and usually wear into grooves. All metals "fret" more or less, although, if the two surfaces are of different metals, the friction is greatly lessened. Thus, we generally find brass working against gun metal or steel, and in the best-made instruments, where aluminium is used, the aluminium is made to work against brass, gun metal, or nickel silver.

Presumably, because hydrochloric acid will dissolve aluminium, all substances containing chlorine seem to attack it, so that, if aluminium is what is technically known as "bronzed" (i.e., a shade generally black, green, or bronze colour is imparted to it by immersing it in a chemical solution of a metal, which the metal to be "bronzed" has the power of reducing to the metallic state), it should never be done with a chloride bronze, as, by the use of it, the aluminium article so treated eventually becomes very rough upon the surface. Brass or gun metal are often so treated, and generally with a chloride "bronze," which is quite safe for them, but does not seem to answer well with aluminium.

Aluminium, being so strong, is difficult to bend when cold, and will often break instead; but, if heated slightly, it may be bent without breaking.

Aluminium is very suitable for the cells of lenses and other fittings of cameras, where little or no friction occurs, on account of its lightness and strength, they are not so liable to bend, besides which aluminium keeps its finish so well without being lacquered, where brass, which requires lacquering, after some little wear becomes dirty and unsightly through the lacquer wearing off and leaving the brass exposed to the air; it is

also very suitable for the stands of cameras, and, but for the unfortunate fact that it is affected by alkalis, it would be very convenient for the various dishes, &c., used in photography, on account of its cleanliness and strength; but, as the salts used in photography are to a large extent alkaline, usually sodium potassium and ammonium, aluminium would be sure to be attacked.

A prolonged immersion in very hard water, strongly impregnated with lime, will attack aluminium slightly.

Some of the alloys of aluminium have been largely used in the manufacture of cheap jewellery, known as aluminium gold.

C. T. SUTTON.

### THE BIG "D"

THE big "D" is a letter replete with interest, possessing unlimited versatility of definition; moreover, is of considerable importance to photographers according to the particular standpoint from which it is viewed. In a stroll through the streets of the metropolis early in the day the big D will be noticed glaring at you from numberless conspicuous stations enclosing three smaller letters in its semicircular dimensions. Everybody knows what it means, but few know of what it is composed with anything like chemical exactitude, its varieties are astonishing and, as far as photography is concerned, annoying as astonishing—dust, particles of every solid substance in existence depending for its composition chiefly on local conditions, even varying according to circumstances.

As far as photographers are concerned, it may be divided into two classes, chemical and inert dust, to say nothing about the adjectival rendering that is sometimes accorded to the big "D" to which the more solid matter gives rise. Chemical dust usually demonstrates its obnoxious presence in confined situations, such as the dark room or laboratory, where such substances as hypo, perchloride of mercury, pyrogallol, potassium sulphide, &c., may have been used, and either sprinkled on the floor or benches in a dry state or in solution spilled that may have dried up, the fine dust from which by the movement of the person being distributed throughout the apartment to settle on the first convenient surface that presents itself; sometimes this occurs to such an extent that the sense of taste is powerfully affected; at other times, although the tongue and palate may fail to detect it, the sensitive plates or paper will unfailingly do so, to the mystification and annoyance of the photographer, who then may perhaps be excused if he develops the big adjectival D. Chemical dust may be either soluble or insoluble; if insoluble, there is usually a nucleus to be found in the centre of the spot from which the action has radiated, or, in the various processes that the plates and papers undergo, the nucleus may be removed and thus set up a difficulty in correctly diagnosing the cause. As a rule, if the centre of the spot appears to have been the seat of more concentrated action than the rest of the fault, we may conclude some particle of not very readily soluble dust was the cause of it.

Metallic dust, usually iron or brass, is very frequently the cause of spots, especially on paper prints. To cause them, the metallic dust must have come in contact with the sensitive surface *before* the silver salt has been removed, for no dust of this nature will do much harm after its removal, that is, of the silver salt. A very soluble chemical dust affects the sensitive surface somewhat differently; providing it consists of bromides or iodides, the spots will probably be transparent, as these substances will not reduce the silver; but, should it be pyrogallol or sulphides, reduction of the metal immediately ensues and we have a crop of opaque spots.

I mention these few substances as the more likely to be found in the work-room of the photographer although there are many other chemicals that will produce similar effects, in fact, particles of any kind of dust that reduce silver salts will do so. Metallic dust on sensitised paper may escape notice until moisture is applied; the reduction then becomes rapid and by the time the prints are washed will have developed into eyesores, to the complete ruin of the proof.

Many printers, to their annoyance and chagrin, find that no sooner is the paper sensitised and dried than apparently clean paper, in the first instance, is bespattered into black specks, some of which remain as merely black specks, and some during the necessary processes of toning and fixing spread out and have a halo of their own. The metallic dust which causes this may have been introduced into the pulp of the paper during manufacture, or have settled on it before the completion of its preparation as sensitised, albumenised, or gelatino-chloride papers; it is in this latter case merely imbedded on the surface, and only waits the necessary moisture to develop its obnoxious presence. Inert opaque particles of dust may settle on plates or papers, and, merely by acting as a screen, prevent the light falling where they lie, and thus produce the clean spots of non-exposure, otherwise pinholes on the negative and white specks on the paper print. When dishes or measures have been standing some little time unused, it is always the best plan to well rinse and rub them out before putting them into use; however clean they may apparently be, as in the most carefully kept dark rooms there is certain to be more or less dust sure to accumulate, and in all probability possess active chemical quality, the dust from spilled solutions being generally energetic in character, the dust of dried sodium hyposulphite being more dangerous in small than in large quantities. The least trace of it

will upset the best toning bath ever made, and produce that yellowish, glazy appearance sometimes found on prints when being toned after contact with it. The toning action, moreover, seems entirely destroyed, and no additional gold in the bath will set it right; when this happens, it is quite hopeless to expect a decent coloured print.

I am inclined to think that many failures in amateur toning are owing to this contamination. The most minute particles of potassium sulphide—although this chemical is not much used by amateurs it is occasionally for precipitating weak silver solutions or intensification of negatives—will, if it gets on to a print at any time, utterly spoil it, as it is not necessary for any free silver to be present to start the action; a tiny yellow speck at first appears that spreads considerably in a short time; if on the white of the prints it is very unightly, and if on the subject entirely destroys it and leaves a yellow patch instead, with no possible remedy. Metallic dust also frequently accumulates in the rebates of the printing frames, and also on the pads, and is produced by friction from the hinges and springs, that in damp weather will help to produce a plentiful crop of defects. Dust is also dangerous when it settles on the prints that happen to be floating on the top of the water during washing if they are left quiescent for some hours. In fact, in almost all stages of photographic work, dust is an insidious enemy, and is to be guarded against, from the coating of the plates and paper to the mounting and drying of the finished work. Work-rooms should never be swept or dusted just before they are required for use, the dark room especially, the more sensible plan is to do any dusting that is required in the dark room after the day's work is finished, then by the next morning it should be free from any dust likely to give trouble. By some this may seem an unnecessary precaution, and I am aware there are dark rooms that never get swept or dusted from one year's end to another, and yet good clean work is turned out. It need scarcely be said that slovenliness in this respect is risky, and usually eventuates in some mysterious defects appearing on plates or paper at some particularly inconvenient time, the source of which remains hidden in obscurity. The old adage of "letting sleeping dogs lie" is, I think, wrong in principle, for, if the dogs are dangerous, it is much better to remove them and get clear of both dogs and danger at the same time.

EDWARD DUNMORE.

### COLOURING PHOTOGRAPHS.

ALTHOUGH photography in colours has been greatly improved of late, it has not as yet come into general use. I am afraid it will be some time before it is taken up commercially by the provincial professional, on account of the expense of its working, and as results quite equalling those obtained mechanically can be coloured by hand with less trouble.

Several years back, hand-painted photographs were not very popular; this, no doubt, was caused by the highly coloured inartistic daubs that were sold in gaudy frames. Now that photographs are artistically painted, there appears to be quite a craze for them, and no one is considered "up to date" unless they possess one of themselves.

If carefully and tastefully executed, colouring does vastly improve a photograph. Some, of course, do not lend themselves to it, for the simple reason that the original view or portrait did not contain much colour. The principal fault of most painted photographs lies in the artist having used brilliant opaque paints, which destroy the beautiful half-tones and details. To obtain success, transparent colours are necessary for the groundwork, as with them the high lights, shadows, half-tones, and detail may be preserved. Of course, opaque colours must be used sometimes, for the number of transparent ones at the disposal of the artist is very limited, but they will have to be very sparingly applied. A knowledge of drawing is not necessary, the outline and lights and shades being supplied in the photograph; but a training in water-colour painting would be of great assistance in tastefully arranging the colours.

An artist who has been using oil colours will find some difficulty in colouring photographs, because in painting on canvas he paints solidly, whereas on photographs the colours are applied thinly, to allow the detail to show from underneath; but this can soon be got over by a little practice and patience. A little experience in the mixing of the various paints to obtain certain tints, and taste with regard to the colouring so as to get the most artistic results will considerably help, but is not essential, as it will come by practice. There are persons that can sit down and paint a photograph in an artistic way straight off without being taught; others, again, take some time to learn, not because they are "duffers," but they have not the talent.

Photographs by any process, except on very rough paper, will colour well, providing they are brilliant and sharp. A bromide opal, no doubt, is best, as the surface being matted allows the colour to be more easily applied than on a glazed print. If the photographic image is contained in a layer of gelatine, no medium will be required. Oil colours are the most suitable to use, and they have the advantage of being easily removed if a mistake is made. It will also be found that they will not fade so quickly as water colours, and the colouring matter, being of a greasy nature, does not soak in and affect the permanency of the image, as water colours are liable to.

The colours at the disposal of the photographic artist are not many, but are ample providing discretion is used in the mixing of them. The

most suitable are: burnt sienna, crimson lake, Prussian blue, burnt umber, and Italian pink (this is a yellow). The above five colours are transparent, or nearly so, and are to be used for the groundwork—that is, to colour the photograph all over with. The other colours given below are to be put in the extra tints and work up the high light and shadows. They are all opaque: flake white, vermilion, indigo, ivory black, light red, and chrome No. 2. All the above may be purchased in collapsible lead tubes at any artist's colourman.

Some makes cost about twopence or threepence each, but it will be best for general work to buy the better makes, being more permanent. A few of the colours run more expensive than others; for instance, vermilion and crimson lake are more than double the price of burnt sienna, but are put up conveniently in smaller tubes. The other necessary articles are three small sable brushes—Nos. 1, 2, and 2. Water-colour sables are much softer than those sold for use with oils, so are much better to use, as they do not leave so many marks. Two bottles of spirit of turpentine will be required. One should be purchased at the chemist's and the other at an oilman's. The former dries quickest, and, being pure, is used for mixing the paints with. The other will do for washing the brushes in. A piece of linen free from lint is necessary to dry them in. The photograph must first of all be mounted and allowed to dry before any colouring is attempted, and the mount covered up with a mask of paper to prevent it becoming soiled by the paint. It ought to be remembered that transparent colours mixed with opaque form an opaque paint.

For an example of the method of colouring we will suppose we have before us a river scene with towing path, trees, and hills in the distance. The first thing to do is to lay on the ground tints with the transparent colours. We will start on the water. To colour this, squeeze out a little of the Prussian blue—very little—on to an old negative glass, which makes an excellent palette. Add some turpentine to thin it, as it will be a great deal too thick in its natural state, and thoroughly mix with a brush which should be kept for that purpose. Take one of the sables—the medium size will be found about right—and start painting from left to right, at the lower part of the water, making the paint thinner as it gets higher up, to give it the idea of distance. The nearer the object is, the darker; and the farther it is away the lighter it should be. If the brush marks show, they may be lightly dabbed all over with the top of the third finger. This has the effect of making a fine stipple. The towing path is done in the same way, only, of course, using different paints. If of a light tone, burnt sienna; but, if dark, a mixture of burnt umber and sienna is the most suitable. The distance must be kept in the same way as the water. The trees near at hand may be painted dark, and those farther away light green. This is made by mixing Prussian blue with Italian pink. For dark green use a greater proportion of blue, and for light more Italian pink. Purple will be required for the hills in the distance. Prussian blue and crimson lake, using more of the former, makes an excellent one. The sky can be painted with Prussian blue, taking care to have it lighter as it gets towards the horizon. When all the ground colours have been put in, it must be allowed to partially dry before touching further. The reflection of different objects in the water must then be coloured, seeing that they are done slightly lighter than the original. The opaque colours may now be used for colouring the shadows and high lights, taking care not to touch the half-tones. Flake white painted over the high lights on the water will greatly improve them. The ruts from cart wheels, and shadows on the towing path may be heightened by burnt umber, and the brightly lighted parts of the trees and grass will look better if touched up with Italian pink. An evening effect can be obtained by painting the lower portion of the sky and upper part of the water over with crimson lake considerably thinned. Most of the other colours not mentioned above will work in for small objects such as boats, roofs of houses, &c.

The greatest care must be taken not to paint over the outlines or allow the colours to run, and the print, when drying, should be kept from all dust.

OSBORN THORNBURY.

#### COIN-FREED APPARATUS FOR VIEWING STEREOSCOPIC TRANSPARENCIES.

MR. JOHN ROSE has patented an invention for this purpose which, according to his specification, consists essentially of a revolving drum, composed of two discs, *A*, connected together by four parallel bars, *a*, arranged to form a quadrilateral. The discs, *A*, are rigidly secured to pivots, *bb'*. The pivot, *b* (fig. 1), is insulated as hereinafter set forth. The pivot, *b'*, passes through the outer casing, and is continued to form a shaft, to which a handle, wheel, or the like, is attached for the purpose of causing the apparatus to revolve. On the said shaft, *b'*, within the apparatus, is keyed the small gear wheel, *c*, actuating the large gear wheel, *d*, which wheel has integral with it the smooth wheel or pulley, *d'*. This latter has a portion of its periphery cut away, so that a lever, travelling on the surface thereof, will fall into the aperture thus formed at each revolution, and act as a stop to its further motion.

The picture cards or transparencies are formed as an endless band (not shown in the drawing), connected together by hinged joints in any convenient manner, preferably somewhat in the same way as the pattern-card of a Jacquard loom mechanism, and the size of such transparency corresponds to the distance between the cross bars, *a*, so that each

complete revolution of the apparatus will display four of the transparencies.

The edge of one of the discs, *A*, is provided with four notches, *x*, placed exactly 90° apart, and devised to engaged in the spring bolt or

catch, *y*, for the purpose of ensuring the exact register of the apparatus, and indicating to the person causing the same to revolve the exact position at which each successive transparency should be stopped.

The coin-freed mechanism consists of the pivoted lever, *e*, provided with a counterweight, *g*, and having at its other end the spring-coin hopper, *h*. This hopper consists of two parts, *h* and *h'*. The part, *h*, is rigidly fastened to the lever, *e*, and the part, *h'*, is pivoted to it, and is normally held close by means of a leaf spring or other convenient device (figs. 1, 2, and 5). To the lower part of the said piece, *h'*, there is attached a bar, *h''*, projecting backwards, and devised to come in contact

with the smooth wheel, *d'*, attached to the gear wheel, *d*. There is also attached to the piece, *h'*, a projecting lever, *i*, which is devised, when the said hopper, *h*, is depressed by the insertion of a coin, to come in contact with a stop or bar, *l*.

The electric-lighting system is as follows:—

A battery, *z*, is placed at any convenient position in the apparatus. The connecting wire, *m*, makes connexion with the outer metal support, *x*, of the frame, and through it and the connecting bar, *l*, with the central pivot, *b*. The bar, *l*, rides on the pivot, *b*, or a wheel placed thereon, which wheel may suitably be formed as a ratchet to prevent the apparatus being turned the wrong way. The pivot, *l*, of the bar, *l*, is

preferably provided with an insulating washer of rubber or the like at its inner end to prevent accidental contact with the disc, A. The disc, A, is insulated from the pivot, n, by means of an insulating washer and collar, o. From the pivot, n, the current passes through m to the electric lamp, z. The other wire, n<sup>1</sup>, makes connexion with the moving parts of the apparatus, when the same is operated as follows:—

The connexion is through the wire, n n<sup>1</sup>, to the spring, o, which may be an ordinary leaf spring or the like, and is so placed as to be in contact with the edge of the wheels, n<sup>1</sup>, as far as this extends. When the cut-

Fig. 3.

out portion of the wheel comes opposite to the spring, the contact is broken between the wheel and the spring, o.

The apparatus is operated as follows:—

When the apparatus is out of action, the parts are in the position shown in figs. 2 and 3, with the counter-weighted end, g, of the balanced lever, a, resting on the pin, g<sup>1</sup>.

Whilst the apparatus is in this position the shaft cannot be revolved, because the projection, g<sup>11</sup>, upon the disc, A, engages with the stop, g<sup>11</sup>, on the rocking bar, o, and locks the apparatus against motion in the

Fig. 4.

forward direction, whilst motion backwards is prevented by the ratchet bar, L.

As soon as an operator places a suitable coin in the slot of the machine and the same falls into the hopper, n, it over-balances the lever, a, and causes the projection, t, to rest upon the projection, i. This motion of the lever, a, and with it the stop, g<sup>11</sup>, releases the projection, g<sup>11</sup>, and allows the disc, A, and the gear wheels, c, d, and wheel, n<sup>1</sup>, to revolve, and at the same time the electrical circuit is completed by the contact of

Fig. 5.

o with n<sup>1</sup> (fig. 4). This causes the lamp, z, to illuminate the apparatus, and the electric current will flow until the wheel, n<sup>1</sup>, has completed its revolution and the parts again fall into the position shown in fig. 2.

The coin which has fallen into n is discharged therefrom into the coin drawer as soon as the bar, h<sup>1</sup>, has risen upon the wheel, n<sup>1</sup>, and thereby

caused the coin hopper to open (fig. 6). In order to cause the apparatus to repeat the display another coin must be inserted in the slot, and the handle again turned, whereupon the operation will be again repeated.

In addition to the central illumination herein described the inventor may,

Fig. 6.

if desired, attain special pleasing effects by additional illumination reflected upon the transparencies. This light or lights may be coloured, and can be controlled by push buttons or other convenient devices within the reach of the beholder, enabling various light effects to be produced at will.

### TAKING PHOTOGRAPHS IN LARGE NUMBERS.

THIS invention, the patentee of which is Mr. R. E. Stapleton, the construction provides for one row of lenses, which may be arranged in either a vertical or horizontal line. In the accompanying drawing the lenses are shown as arranged in a vertical line with a duplicate row of lenses shown in dotted lines for the purpose hereinafter explained. Fig. 1 illustrates a back view, and fig. 2 a corresponding front view, of the camera; fig. 3 a sectional view taken on line, x x, of figs. 1 and 2. In order to expose the position of the lenses, the repeating slide, a, is drawn back in fig. 1, and the shutter, b, in fig. 2, showing in line the five lenses, c c c c c, which is to be taken as representing a convenient number for the purposes of illustration only. d is a spring catch secured to the camera casing, and adapted to click into a series of holes, e, regularly pitched in the framework of the repeating slide, a, in succession, these several holes being arranged in number and pitch, so that each successive engagement effects an exact adjustment of the impression plate to expose a section thereof to the series of lenses in the manner required for the purpose of my invention. In this way the whole surface of the impression plate may be covered by portraits or pictures, the full complement for each impression plate comprising, of course, the number of lenses set

Fig. 1.

Fig. 2.

Fig. 3.

in line multiplied by the number of repetitions of sectional exposures for which the said impression plate is designed.

The apparatus may be varied in certain respects without departing from the essential features of the invention. For example, although we have mentioned one row of lenses only, this could be duplicated, as shown in dotted lines in figs. 1 and 2; but, although the number of exposures or adjustments of the impression plate is halved thereby for the same number of portraits for a given size of impression plate, the same variety of portraits would be correspondingly reduced, or the number of impression plates required would be doubled. It is therefore found in practice that, for the purpose of the invention, one row of lenses is generally more convenient than two rows.

And, furthermore, the spring-catch arrangement for adjusting the impression plate to a succession of positions by clicking into a series of holes, as shown and described, is only to be considered essential in respect of the purpose effected, and as indicating what is suitable therefor, for which other devices may be substituted.

## THE TELLA CAMERA.

At the meeting of the London and Provincial Photographic Association, on September 28, Mr. W. E. Dunmore, of the Tella Camera Company, Limited, showed and described the Tella film camera in its latest modified design. During the last twelve months several improvements have been effected over the original form, which was much larger and heavier than the latest pattern. It is now furnished with rising and cross fronts. A swing back is of no use in hand cameras, therefore a good rise of three-quarters of an inch, horizontally or vertically, has been provided. The camera focusses now from two yards' distance to thirty yards or infinity. The whole front of the camera, carrying the shutter and lens, &c., is made to slide completely off, giving access to the interior of the camera for dusting purposes, and similarly to the back combination of the lens. The method of using the cut films, for which the camera is designed, is unique. The films are taken in packs of twenty-five, with a small separating device between each film at one end. There is no straw board or any other agency of a deteriorating nature between the films used for this camera.

The full charge is fifty films, although Mr. Dunmore spoke to having used as many as sixty without mishap. The changing is very simple. There is no dropping of the film, and so no chance about it. It is pulled over, and during the course of this pulling only the edges or rebate of the film come into contact with the camera. Nothing whatever, from first to last, comes into contact with the film in the way of cards for separating purposes or during the changing action, hence there is less reason for the film to go wrong. One of the features of the Tella is that it tells when everything is right or wrong. If there is no film, it says as much, and if there is a supply it states the fact. Mr. Dunmore had with him a useful model of the camera with glass sides, which enabled his audience to observe every motion of the changing mechanism in the most conclusive manner. After exposure the films are conveyed into a chamber in the bottom of the camera, from which any one or the whole of the exposed films may be abstracted at pleasure.

The little separators, which form an essential part of the changing movement, fall into another chamber. The registration of the number of exposures is dependent, not upon the actual motion of the changing device, but upon the film itself. It is the film which actuates the mechanism for registration, and if the film, by any possible means, was not changed, though it might appear to have done so, it would not be registered as having passed over. The Company supplied films for the camera, but it was another point in favour of the instrument that any quarter-plate cut film could be used with the separator referred to. There is no special preparation of the film at all required. This is a great advantage, as many have had reason to learn. A Cooke lens, working at f-5, is fitted to the cameras. There is a Yale shutter, with pneumatic regulation, working from half to one one-hundredth of a second and time, which is placed between the combinations of the lens. Mr. Dunmore said that it was hoped very soon to have a 5 x 4 pattern on the market. He showed some of the trial negatives made with it. A cheaper pattern was also coming out, of the box sort, fixed focus, with magnifiers, but no rising front. The camera and parts were examined with much attention by those present, and a vote of thanks was passed to Mr. Dunmore.

## THE WELLINGTON FILM.

At the meeting of the Photographic Club, on September 27, Mr. Harry Wade read a paper descriptive of the Wellington Film. This film has a paper support, and consists of a very rich emulsion. It lies perfectly flat without special means being taken to this end, and may be exposed in an ordinary dark slide without support. It is thus especially recommended to travellers, and has points which will attract the ordinary worker. Development of the films presents no greater difficulty than in the case of glass plates, and they are treated in precisely a similar way, pyro and ammonia being recommended in preference to soda. There is less danger with the former developer of the gelatine being attacked, which might result in the film refusing to leave its paper support. It is asserted that no danger attends the practice of developing several films together in the same dish, abrasion not readily taking place. As a matter of fact, the films may be developed in a number, as prints are toned, any danger of the films adhering one to another being overcome by maintaining the circulation of the films. The paper support upon which the film is coated is translucent, and the progress of development may be readily watched and judged. After development, the films are transferred to an alum bath and finally fixed, an acid fixing bath being recommended by the makers of the paper. Mr. Wade, however, found an ordinary fixing bath to be just as efficient, and said that he never used any other. When the films have been well washed they are squeezed on to a clean glass or ferrotype plate and allowed to slowly dry, upon which they will either peel off by themselves or with very little persuasion. The negatives produced in this way are now ready for printing, the paper support being quite sufficiently translucent. Should objection be raised, however, to printing through the paper, the gelatine film may be easily separated from the paper by the help of a penknife. Mr. Wade demonstrated this separation, which seemed to present no special difficulties,

and is easier done than described. The back of such a stripped film presents a matt surface, which lends itself well to the pencil for spotting, mending defects, or faking generally. One of the advantages offered by the film is that of printing from either side, a fact which will find appreciation amongst carbon workers. An entire absence of halation is claimed for the Wellington film, and, in proof of this, a negative of a figure taken against a curtained window was shown. There was no trace of the defect named, but it was generally thought that the proof would have been still more convincing had the negative been exposed for the figure instead of for the curtains. The speaker also claimed greater keeping qualities for his film than for glass plates, but did not substantiate this by ocular proofs. In conclusion, he passed round some very fine specimens of work done upon the films.

Mr. F. A. Bridge, in giving his opinion of the films, thought that their chief advantage lay in their great toughness, combined with lightness; and, the Chairman having endorsed these remarks, a vote of thanks was passed to Mr. Wade for his interesting lecture.

## A SITTER'S PROPERTY STOLEN.

## PHOTOGRAPHERS' LIABILITY.

At Marylebone County Court, on Tuesday, Sept. 26 before Judge Stonor, Miss Annie Elizabeth Johnston, 1, Wellesley-mansions, West Kensington, London, W., claimed damages from Messrs. Hellis & Sons, photographers, Westbourne-grove, W., with respect to the loss of a watch and some cash, alleged to have been stolen under somewhat peculiar circumstances. Mr. W. Sanderson and Mr. V. D. Knowles were counsel for the plaintiff, and Mr. Cohen, counsel, defended.

The plaintiff, a young lady of attractive appearance, told her story as follows: On May 31 last she went to the studio of Messrs. Hellis & Sons to have her photograph taken. As she desired to be "taken" in evening dress, she was shown by a lady attendant to a small room, over the door of which was written "private." This room had only one entrance, so far as she could see, and the door was to be easily seen from the desk at which the lady attendant sat. After changing her attire and preparing for the sitting, she placed her watch and purse on the table and pulled a piece of paper over them. Then she left the small room, closing the door after her, and repaired to the photographic studio, while the lady attendant went back to her desk. On coming back to the small room, after the sitting, she was dismayed to find that her watch was gone and all the silver—5s. or 6s.—had been extracted from her purse. A peculiar feature of the theft was that the small chain and "charms" to which the watch had been attached were still carefully esconced under the brown paper. She immediately called to the lady attendant, and said, "My watch and money are gone, and you are responsible;" and the attendant replied, "Yes, but no one could come in here and go to the room without me seeing them." The assistant also added that such a thing had not occurred since she had been engaged at the studio, but that something of the kind happened in the time of her predecessor. The manager was also called, but was as mystified as the rest of them. Then she sent for a constable.

The Judge: Was there any one else about?

The plaintiff replied that a boy came into the photographic studio, while she was sitting, with the photographer's lunch. Continuing, Miss Johnston said that, after the constable was called in, she asked for the boy, but was told that he had gone to dinner. The lad did not return until ten minutes or a quarter of an hour after his hour. He was then searched, but, alas! watch and silver were not to be found.

Cross-examined: The door to the small room in which she left the watch and other articles opened directly on to the stairs, and upon these stairs some men were working. She could not remember whether she latched the door or not on leaving for the photographer's room, but she was sure that she pulled the door behind her. She did not think it necessary to ask the lady attendant to mind the watch and purse, because the room was marked "private."

Re-examined: The young lady attendant distinctly told her that it would be absolutely impossible for any one to pass into the small room without her seeing the person.

Counsel for the defence submitted that there was no case whatever against Messrs. Hellis.

The Judge: I think that there was negligence on the part of the plaintiff in not taking the watch and purse with her, instead of leaving them in the room, although it was marked "private." And I also think that she might have drawn the attention of the young lady to the watch and purse which she had left in the room.

Mr. Sanderson, for the plaintiff: But, if my friend's contention were allowed, it might be possible for any person, under the guise of a photographer, to carry on a wholesale system of robbery.

The Judge: But you must distinguish between what was necessarily to be left in the room—such as hat or coat—and such things as a purse or watch, which could be put safely in one's pocket.

Mr. Sanderson: But suppose the case of a person to be photographed, not in evening dress, but in tight.

The Judge: That is not this case. The plaintiff, I suppose, had a pocket in the back of her dress?

The plaintiff: No; it was in front.

The Judge: I must nonsuit the action, but I shall allow no costs.

Counsel for the plaintiff asked for leave to appeal, but his Honour refused the application.

### THE FORTHCOMING SOLAR ECLIPSE.

"Persons interested in the forthcoming total solar eclipse of May 28, 1900," says our contemporary *Knowledge*, "will be glad to learn that great care and forethought are being exercised by some of our leading astronomers in the necessary preliminaries for ensuring success, as far as is practicable, in the manifold problems which present themselves for solution in such expeditions. The path of the moon's shadow in the eastern hemisphere reaches from Oporto to Algiers, and the duration of totality ranges from one minute thirty-six seconds in Portugal to one minute six seconds in Northern Africa. The sphere of activity will be mainly in places between 8° longitude east and west of Greenwich, and latitudes 35° north to 42° north, thus affording an exceptional opportunity of easy access at a moderate cost to those who wish to visit the scene of operations. It is urged that Algiers should be occupied on account of its low cloud ratio, its accessibility, and its excellent harbour; in the region south of Madrid several railway lines cut the shadow track, so that the difficulty of transporting instruments will thus be minimised; some inconvenience, however, may be caused by the slowness of the trains, which run about fifteen miles an hour, and the long intervals between them, there being in most parts only two a day, and only about one an hour out of even Lisbon. Mr. Maunder has been very active in bringing useful information together for the benefit of those taking part in the expedition, and in this connexion the following particulars may be helpful: To Lisbon (or Oporto) and back, 10*l.*; to Cadiz, giving access to the centre of Spain, and back, 14*l.*; to Alicante, a port on the east of Spain, where the eclipse will be visible, 16*l.* Algiers is the final place to which the steamer will proceed, and remain there to act as an hotel for the party. The cost for the entire trip for those going to Algiers and remaining on board during the stay at Algiers would be 22*l.* 10*s.* These figures represent the cost to members of the British Astronomical Association. To friends the charge will be guineas instead of pounds. The Eclipse Committee ought to know definitely before the end of the year the exact number of passengers going and the ports which they may have selected, in order to be able to complete arrangements. As yet 114 or 115 names have been given in; but, in order to justify the Committee in completing the arrangements, they ought to have at least 200 taking part in the expedition. The entire trip will take eighteen days."

### SUGGESTED PHOTOGRAPHIC SOCIETY FOR CAMBRIDGE.

"*Helios*" writes to the *Cambridge Daily News*: "Now that the winter evenings are drawing in upon us, many young men, and, indeed, older ones, too, are thinking of how best to spend a little of their spare time. Cambridge is generally considered to be behind the times, and in the matter of a photographic society the assertion is certainly true. I am perfectly well aware of the fact that a small society exists within the walls of the Y.M.C.A., but for a town like Cambridge that is, in my humble opinion, not enough. We want a free and open society, i.e., one that does not necessitate one's belonging to a certain religious sect, and I am looking anxiously forward for some one to call a meeting for the purpose of seeing if such a society cannot be formed. About eight years ago we had a fairly good society in the town, but the members (or was it the officers?) ceased to give it any attention, and it died, with plenty of money in its pocket, so to speak, for, if I mistake not, a substantial sum was handed over to the hospital. There was a membership, I believe, of about twenty-five. Since then photography has advanced, and become advanced and become simplified, with the result that many others have joined the ranks. Can Cambridge support such a society? I fancy I hear some ask. In reply, I beg to state that, according to the latest returns, there are at least twenty towns of the same size as Cambridge, and no fewer than twenty-eight towns of smaller size, all now supporting photographic societies. In addition to the large number of clubs now existing, many provincial newspapers are devoting weekly or monthly columns to the art of photography, and I venture to say we could do with such a column in this town. We have some good amateurs as well as professionals in the town if they would but come forward. One gentleman has made his name by patenting a camera front, another is a well-known writer on photography, another a Fellow of the Royal Photographic Society, whilst many others hold high awards. Next year the Photographic Convention is to be held at Newcastle, and Oxford is hinted at as being the next, and why should not Cambridge follow? A Convention here would be the means of bringing into the town between 200 and 300 visitors, the majority of whom would stay the week. Now, then, ye disciples of the black art, stir yourselves, and see if a society cannot be established, and at least one night a week devoted to the art that is so dear to many of us."

## News and Notes.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Ordinary Meeting, Tuesday, October 10, at 5*4*, Pall Mall East, at eight p.m. The President will deliver his annual address. The presentation of medals awarded at the Exhibition.

**THE Southsea Amateur Photographic Society's Twelfth Annual Exhibition** is fixed for January 29, 30, and 31, 1900. Entry forms and particulars are obtainable from F. Mortimer (Hon. Secretary), 10, Ordnance-row, Portsea.

**THE Southport Y.M.C.A. Camera Club's Third Annual Exhibition** of photographic work will be held in the Y.M.C.A. Hall, Eastbank-street, Southport, from six to ten o'clock in the evenings of Tuesday, Wednesday, and Thursday, October 17, 18, and 19, 1899.

**THE Montreal Camera Club's Fifth Annual Exhibition** will be held, November 21 to 25 inclusive, in the Club rooms and studio, 4, Phillips-square. The following are the open classes: Class A, prints (by any process), open to all; one silver and one bronze medal. (All prints will be first judged in this class). Class B, Portraits, open to all; one silver and one bronze medal. Class C, Lantern Slides, open to all. (In sets of four. Judged as a set.) One silver and one bronze medal.

WE regret to state that Mr. John Jackson, one of the oldest photographers in the country, died at his residence, South Dene, Rochdale, on Tuesday, September 26. He had not enjoyed good health for the last eighteen months, and had been confined to his bed for twelve or thirteen weeks. Dr. Sharples and Dr. Lord, of Castleton, were his medical attendants. Deceased, who was seventy-two years of age, was the last of five brothers who formerly carried on business as photographers at Oldham and Mill Middleton Junction. About 1865 he commenced business on his own account as a photographer in The Walk, Rochdale. For twenty-nine years he resided at South Dene. In 1885 he removed his business from The Walk to premises adjoining his residence, where it has since been carried on. Mr. Jackson was an advanced Liberal in politics, but took no active part in public affairs. He is survived by his widow, three daughters, and one son. The funeral took place on Friday, the 29th ult.

## Patent News.

THE following applications for Patents were made between September 18 and September 23, 1899:—

**ANIMATED PHOTOGRAPHS.**—No. 18,924. "Improvements in Apparatus for Viewing and Exhibiting Living Pictures or Animated Photographs." G. F. HATTON.

**CAMERAS.**—No. 18,828. "Improvements in Photographic Cameras." R. S. ATWATER.

**CAMERAS.**—No. 18,829. "Improvements in Photographic Cameras." R. S. ATWATER.

**DARK ROOM.**—No. 19,008. "Photographer's Clothes Trunk and Dark Room Combined." C. M. JORDAN.

**CAMERAS.**—No. 19,172. "Improvements in or relating to Photographic Cameras." A. L. ADAMS.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
9.....	Bradford Photo. Society .....	Demonstration: Slide Making. F. Nicholson.
9.....	Camera Club .....	Exhibition of a New Phonograph with Musical Selections. Lindsay Johnson, M.A., M.B., &c.
9.....	Oxford Camera Club .....	Exhibition of Slides lent by the Royal Photographic Society.
10.....	Ashton-under-Lyne.....	From Cornwall to Canterbury. Llewellyn Morgan, M.D.
10.....	Birmingham Photo. Society ..	The Manchester Ship Canal: its History and Construction. C. R. Sayer.
10.....	Hackney .....	Animal Photography. J. O. Grant.
10.....	Leeds Photo. Society .....	Technical Control for Pictorial Purposes. W. Thomas, F.R.P.S.
10.....	Royal Photographic Society ...	The President will deliver his Annual Address, and will present the Medals awarded at the Exhibition.
11.....	Camera Club .....	Ladies' Evening: Exhibition of Lantern Slides, by Members of the Field Club.
11.....	Groydon Camera Club .....	Last Day for Delivering Pictures for Exhibition.
11.....	Photographic Club .....	Members' Open Night.
11.....	West Surrey .....	Competition: Lantern-slide Making.
12.....	Camera Club .....	Paper by Captain W. de W. Abney, C.B., F.R.S., &c.
12.....	London and Provincial .....	Lantern Night.

**Liverpool Amateur Photographic Association.**—The Opening Meeting of the thirty-sixth winter session of this Society was held at the rooms in Eberle-street on September 30. Mr. Paul Lange was in the chair.—The Hon. Secretary (Mr. F. Schierwater) read the programme arranged by

him for the session. The arrangements as to lectures and demonstrations excited great praise from those present. Two of the more notable fixtures are Mrs. Main, whose lecture last year on "Mountaineering" was so well received, and whose subject will this year be "Mountaineering in the Arctic Circle," and Mr. Talbot Kelly, the well-known local artist. Mrs. Main's lecture will be delivered in the small concert room, St. George's Hall, on November 16. At the conclusion of the usual business meeting, Mr. W. PRIOR CHRISTIAN delivered a lecture on

#### SOME PHASES OF TUSCAN ART,

illustrated by numerous lantern slides. Mr. Christian handled his subject in a most masterly and at the same time most poetic manner, tracing the development of Tuscan art through the channels of painting and sculpture from the earliest times. The lantern slides included specimens of Byzantine art, the notable cathedrals of Pisa, with its leaning tower, Florence, and Siena, frescoes, and mosaics. The architectural slides were of the finest description, and several elicited marked approval from those present. At the conclusion a hearty vote of thanks was passed to the lecturer.

#### FORTHCOMING EXHIBITIONS.

1899.  
 October 6-Nov. 4 ... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.  
 „ 6-Nov. 11 ... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.  
 „ 11 ..... Ludlow Photographic Society. Hon. Secretary, 14, Mill-street, Ludlow.  
 „ 18-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.  
 „ 22-Nov. 19 ... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
 November 15-17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.  
 „ 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.  
 „ 27-Dec. 18 American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.  
 December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.  
 „ 11-Jan. 1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.  
 „ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.  
 1900.  
 April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### STAINS ON PRINTS.

To the EDITORS.

GENTLEMEN,—I noticed, in your Answers to Correspondents of the 15th inst., that "G. B. H." asked you the cause of a stain resembling hyponitric markings on prints, and I have seen several similar queries, especially about this time of year, and to all you reply 'faulty manipulation,' which, no doubt, is the cause of many marks but not every one, as instance a difficulty I had this summer, when batch after batch were stained yellow in cloudy patches (like sample enclosed), and which any one offhand would describe as caused by carelessness. I did the work all through myself with the greatest care and cleanliness. When the marks appeared I set about to find their cause, trying fresh samples of hypo and paper, but without effect; I then thought that the water might be at fault, so tied four thicknesses of blanket loosely round the tap to form a filter; the next batch of prints had not a single stain, and on removing the flannel

from tap I found that it contained a film of slimy matter (as sample enclosed), which smelt horribly, and, when stirred in a small quantity of water, discoloured it, like aniline dye, its presence in the water being possibly accounted for by the low state of the reservoirs, owing to the drought.

Trusting that the above experience will be of service to "G. B. H." and others,—I am, yours, &c., T. EVERITT INNES.

108 Wellington-road, Heaton Chapel, September 26, 1899.

#### MR. BLAND'S SUNBEAMS.

To the EDITORS.

GENTLEMEN,—On page 614 you put the question to me, "Are not sunbeams penetrating through a stained-glass window, as at Wirksworth, always parallel?" Beyond a reluctance to talk in public about my own print, I have not the remotest hesitation in taking up your challenge. The rays on the window recess referred to are entirely untouched; they are there as they were made by the sun and the glass, and therefore the fact that they are not parallel gives a distinct "No" to your question. Sunbeams penetrating through a window do not *always* emerge parallel. It may be, then, that photography has once again demonstrated that the things that are are not as we conceive them to be.

I enclose the original negative, a print from it, and the portion of the enlarged print showing the rays.—I am, yours, &c., W. B. BLAND.  
 Duffield, Derby, September 30, 1899.

[We have examined the negative and the prints Mr. Bland was so kind as to send for our inspection. The negative is untouched, and the positives are faithful reproductions of it.—EDS.]

#### THE BOOTLE PHOTOGRAPHIC SOCIETY EXHIBITION.

To the EDITORS.

GENTLEMEN,—I should feel extremely obliged if you would draw attention in your valued paper to the fact that entry forms for above Society's Exhibition must reach me at 188, Strand-road, Bootle, Liverpool, on or before October 10, and the entries themselves be delivered, carriage paid, by October 21.—I am, yours, &c., THOS. A. DODD.  
 188, Strand-road, Bootle, Liverpool, October 2, 1899.

#### THE AMATEUR PHOTOGRAPHIC SOCIETY OF MADRAS.

To the EDITORS.

GENTLEMEN,—Will you kindly allow me an inch or two of your space to say that I have once more taken up the duties of Hon. Secretary of the Amateur Photographic Society of Madras, and that on this occasion I have also been appointed Editor of the Society's Journal?

I should be much obliged to editors of photographic papers if they would kindly exchange papers with us, and I trust that, when we have got into working order in a month or so, our Journal will contain matter more original and useful than it has for some time past.

I should also be glad if manufacturers and dealers would send me price-lists and memoranda of anything new. The latter would be still more useful if accompanied by small samples for demonstration at our monthly meetings. My address is, The Masonic Hall, Mount-road, Madras.—I am, yours, &c., F. DUNSTERVILLE, F.R.P.S.,  
 Secretary Amateur Photographic Society of Madras.

Madras, September 14, 1899.

AMONGST the few exhibitors of lantern slides at the Royal Photographic Society's Exhibition is Mr. Graystone Bird of 38, Milson-street, Bath. This gentleman shows a set of six, consisting of figure and other studies: they are remarkably bright and interesting slides.

MESSRS. RAE BROS. of 134, St. Vincent-street, Glasgow, send us their catalogue of lanterns and lantern slides. Including the optical part, the catalogue runs to 190 pages. It has many phototypic and other illustrations, and at this season of the year it should be found valuable for reference by all those interested in optical projection work.

MR. W. H. ASSENDER, of the Trilby Incandescent Lime Works, 2, Vestris-road, Forest Hill, London, S.E., informs us that he has severed his connexion with the Nottingham Incandescent Lime-cylinder Syndicate, Limited, and its kindred businesses, and has established himself at the above address as a manufacturer of lime cylinders for use with either high-pressure or blow-through oxyhydrogen mixed gas jets. Mr. Assender adds: "After many months' scientific research, I have discovered a method of treating solid block lime, which not only enhances the brilliancy and whiteness of its incandescence, but improves the durability of the lime." It is Mr. Assender's determination to lay down a hard-and-fast rule to supply none other than actual wholesale dealers, and personally supervise every parcel of limes which leaves his factory.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

- A. J. Ashbolt, 10, Exmoor-road, Southampton.—Photograph of D. Greenlees.  
 J. Robb, sen., 164, Springfield-road, Glasgow.—Photographs of Royal Infirmary, Glasgow; Belvedere Hospital, Glasgow; Centre of Glasgow Necropolis; North end of Glasgow Necropolis; Infirmary-square and Castle-street, Glasgow; Infirmary-square, Glasgow; South end of Glasgow Necropolis.

RECEIVED.—"GUILD;" WILKINSON & Co.; F. E. G.; TRICOLOUR; "NEMO" and others. These in our next.

R. E. WILKINSON.—We have forwarded your letter.

A. S. MARSHALL.—It is against our rules to recommend particular makes of apparatus, but we believe the camera named to be excellent value.

HURSTPIERPOINT.—We believe the firm named to be respectable. You appear to have addressed your letter to Tottenham; it should have been Nottingham.

HIRE OF APPARATUS.—VISITOR. Both Messrs. Morley & Cooper, and Sands & Hunter, we believe, lend apparatus on hire. The address of the former firm is, 70, Upper-street, Islington, N.; and the latter, 20, Cranbourne-street, W.C.

ASCERTAINING COPYRIGHT.—X. L. The only way to ascertain if the picture is copyright or not is to search the register at Stationers' Hall. If, however, the picture was produced in France or Germany, as you suspect, the register at Stationers' Hall will not contain it. Nevertheless, the picture may be copyright here under the International Copyright Act.

RED TONES ON P.O.P.—H. W. BRYANT says: "Can you oblige by telling me how I can obtain brick red tones on matt or glossy P.O.P., avoiding double tones?"—Only by very slightly toning. When such tones are desired, it is a good plan, after washing out the free silver, to immerse the prints in a weak solution of salt and water for a short time, and then wash again before toning.

PINK TINGE WITH AMIDOL.—W. H. S. says: "I have been developing bromide prints with amidol, and find many are tinged with pink as the one enclosed. 1. How can I avoid this? 2. Should I use a clearing solution? 3. If so, what?"—1. As some prints only are tinted it shows that the cause is in the manipulations. Try more washing after fixing. 2 and 3. Not necessary.

EDINA.—The work is exceedingly good; but, even so, the London labour market is sadly overcrowded, and your chances of improvement would be somewhat remote. In our opinion you would have a better opportunity in a large provincial town. Why do you use such wretched slang terms as "ref," "crib," and "specs?" This sort of thing would certainly militate against you in London.

ADDRESS WANTED.—J. R. R. says: "In the last BRITISH JOURNAL PHOTOGRAPHIC ALMANAC there appeared an advertisement, 'Art Lantern Slides, Braun, Clément, & Co.' Do you know if these can be bought in England?"—We are not aware that they can. The Autotype Company are agents for Braun's paper reproductions, but we are not sure that they are for the lantern slides. Better write them at 74, New Oxford-street, W.C.

BURNISHING.—BURNISHER says: "I should esteem it a great favour if you would kindly give me particulars for using burnisher (roller) for cabinets, &c. (portrait). The one I have is a double nickelled roller burnisher. What is the best paste to use? I have never worked a burnisher before."—The usual lubricant is a solution of Castile soap in alcohol, about two grains to the ounce. Possibly the burnisher does not necessitate any lubricant at all. Some forms do not.

SEPIA TONES ON BROMIDE PAPER.—SEPIA writes: "I should esteem it a great favour if, in your Answers to Correspondents, you could give me a formula for obtaining warm sepia tones on bromide enlargements other than the alum and hypo boiling method."—If you refer to page 180 of our issue for March 24, you will find an article on producing various colours on Velox papers by development only. Possibly, the method there described, or a slight modification thereof, will answer with the paper you are using.

STUDIO EXTENSION.—J. BEALE writes: "I am going to have a studio built in the garden, backing on the house. I propose to have it twenty-three feet long and eleven feet wide. Would there be any advantage in having at the end a pair of folding doors, so that the camera can be placed outside in the garden?"—Yes, certainly. Twenty-three feet is short for a studio for portraiture, particularly with groups, but with the suggested folding doors you will obtain all the advantages of a longer studio when required.

DUST TROUBLES.—SIDNEY B. says: "I am much troubled with dust in my place, which cannot be avoided. When the prints on P.O.P. are drying, the dust sticks to them and cannot be got off. I have had no experience with albumen paper, but would the dust stick to that so that it could not be rubbed off when dry?"—Any dust settling on albumen or collodion prints can be rubbed off when they are dry. Furthermore, albumen and collodion prints may be dried between blotting-paper, so that the dust need not come in contact with them at all.

IRON PRINTING.—OTHELLO writes: "Can you tell me of any iron printing process to resemble bromide, or any method of turning ferro-prussiate paper (blue prints) to a black?"—A long article on the iron printing process appeared in the ALMANAC for 1889, see pp. 367-373; see also Mr. Lambert's series in the JOURNAL a few months ago. These methods are given for producing brown and black tones, but we doubt if any of them will give colours similar to those on bromide paper except the platinotype process, which in reality is an iron process.

EXAGGERATED STEREOSCOPIC RELIEF.—STEREO sends us a stereoscopic slide of a small statuette, and asks the cause of the exaggerated relief in it when seen in the stereoscope. He says the lenses were three inches apart, and other subjects taken with the same camera do not show any too much relief.—The reason for the great relief is that the lenses were too far apart for an object so near to them. By the look of the slide we should say that the statuette was not more than three feet from the camera, possibly less. In this case a separation of the lenses of a couple of inches, or less, would have sufficed.

MEMBERSHIP OF R.P.S., &c.—UPPERTON writes: "1. Will you kindly inform me how to become a member of the R.P.S.? 2. I am about to open a studio in a village where there are a great many amateurs, and intend catering for them in apparatus, materials, &c. Will you please tell me how I am to become a qualified dealer, as the wholesale firms inform me that they cannot supply professional photographers at dealers' rates?"—In reply: 1. The Secretary, 66, Russell-square, W.C., will send you particulars. 2. We imagine that, in order to secure dealers' terms, you must relinquish professional photography, and trade as a dealer pure and simple.

STUDIO REPAIRS.—O. P. Q. writes: "I find my studio leaks badly in the roof for want of paint. I have applied to the landlord, and he refuses to do what is necessary, saying it is my place to do the repairs. I have had the place two years, and have it on a seven years' lease. Is it not his place to do the necessary repairs when they are required?"—We should say certainly not on a seven years' lease. Leases are generally granted on the condition that the tenant keeps the premises in good repair, and also that he leaves them in such. No doubt if our correspondent reads through the lease, he will find that he has covenanted to do so.

RESIDUES.—AMATEUR says: "I have been saving my residues for some time past, and I now think I have sufficient to yield four or five ounces of silver, according to my estimate. Will you kindly tell me the best refiner to send them to?"—We must refer this correspondent to our advertisement columns, it being against our rule to recommend any particular advertiser. We might say, however, that "Amateur" would do well to let his residues accumulate until he gets more. Four ounces of silver at its present price will not realise more than about nine or ten shillings, according to the purity, and after the cost of reducing is deducted there will not be much left.

RESIDUES, &c.—A. P. S. asks: "1. Can you give me the address of Captain Abney? 2. What is the quickest means of throwing down silver from (1) old amidol developers and (2) from hypo? We have about 200 gallons of hypo per week, and our tubs cannot clear themselves quick enough. We are at present using scrap zinc. Any information on the saving of waste in chemicals and paper will be gladly received."—In reply: 1. Science and Art Department, South Kensington, S.W. 2. There is no silver in the developer to throw down. 3. In place of the zinc add a solution of sulphide of potassium, that will precipitate the silver as a sulphide. Care must be taken that no more is used than is necessary, as an excess will redissolve it. Add the sulphide carefully, and when it ceases to cause a further precipitate, stop.

YELLOWED WHITES OF PRINT. ANXIOUS says: "Enclosed is a cabinet print. It has been exposed under a mount in show-case for one month during summer, where the sun from sunrise to mid-day was full on it. You will observe that the unprotected whites have yellowed. Is this due to faulty manipulations, or would any vignette go in a similar way under the circumstances? Also please give your opinion of photograph as a specimen of commercial photography produced in studio 15x8 feet."—Yes, faulty manipulation is the cause. There is no reason why vignettes should go in a similar way if they are properly treated. See leading article in the issue for the 29th ult. The photograph is fair. The fault of it is, the face is too flat, through too strong a front light being employed. Stop off more of that, so as to obtain greater *chiaroscuro*.

TEST FOR HYPO.—R. H. S. says: "1. Could you give me a reliable test for hypo, and correct proportions for use with bromide papers? 2. We use 1 cwt. to 80 gallons of water, and mix fresh every three days. It is in constant use, about 500 yards, 18 inches wide, passing through in each day. I do not think it necessary to use it at such a strength or change it so frequently, as it is sometimes quite clear when thrown away."—1. Two very delicate tests for hyposulphites are given on pp. 975 and 976 of the ALMANAC for the current year. 2. The solution is a trifle weaker than is generally used. We should think it is very inadvisable to use the solution even the second day if the stability of the results are a consideration. Hyposulphite of soda is very cheap. Read the leading article on this subject on p. 611 of our issue for September 29.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the world over as a daily reference guide in practical work. The formulæ will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's

advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

THE Head Master of the Orange-street Board School, Southwark, London, S.E., writes to us as follows: "In this large Board school, situated at the very centre of the most poverty-stricken district of London, we find great difficulty in attracting the poor lads and interesting them in their lessons. They go to work before, between, and after school hours, and have no opportunity for relaxation or self-improvement out of school. I have induced the School Board to fit one of my rooms with cased-in black blinds, and am striving to awaken an intelligent interest among the boys by the free use of lantern lessons, but the slides at my disposal are very limited in number and range of subject. I am sure many of your readers have slides (or negatives from which I can make slides) of places possessing geographical, historical, or Biblical interest, or illustrating geographical terms, industries, &c., for which they have no further use, but which would be of great value for my purpose. I shall be most thankful to receive any which the kindness of your readers may induce them to send. I should also be glad of any discarded lantern large

enough to allow the use of incandescent light (my own iron one being unsuitable), or lantern-slide making apparatus, and would gladly pay carriage if desired." We are sure that many of our readers will be pleased to help in this good and humanising work. Those of them who do not know the Orange-street district can have no conception of the squalor, misery, and ignorance by which it is characterised. Lantern slides, negatives, and (may we add?) the discarded lantern asked for, should be addressed to the Head Master, Board School, Orange-street, London, S.E.

\* \* \*

MR. R. W. CRAIGIE, the Hon. Secretary of the Photographic Salon, informs us that the pleasant little annual function known as the "Salon Smoking Concert" takes place on Tuesday evening next, October 17, at the Dudley Gallery, Egyptian Hall, Piccadilly, W. The entertainment will be chiefly provided by members of the Savage Club.

\* \* \*

THE International Congress of Photography is to be held in Paris from Monday, July 23, to July 28, 1900, and form the third International Congress following those held at Paris in 1889 and at Brussels in 1891; its purpose is: 1. To re-examine decisions arrived at by the two last Congresses on problems before the Society, and to investigate if such are capable of further improvement or perfection. 2. To inquire into the various new photographic questions arising since the last meeting. Practical demonstrations of working methods, lectures on special subjects, and visits to scientific and industrial institutions are included in the programme. The fee for membership is fixed at 10 francs, and the funds derived will be used to defray costs of printing, correspondence, and all incidental expenses of the Congress. Those intending to be present are requested to address the General Secretary, Monsieur S. Pector, 9, Rue Lincoln, Paris. On the termination of the Congress the official reports of the sessions will be published, and a *résumé* of the transactions forwarded to all members.

\* \* \*

THE Second Traill Taylor Memorial Lecture will be delivered by Major-General Waterhouse on Tuesday evening, November 14, at the rooms of the Royal Photographic Society, 66, Russell-square, London, W.C. The subject will be "The Teachings of the Daguerreotype."

\* \* \*

MESSRS. G. WEST & SON, the well-known marine photographers, inform us that their lantern lecture, "Our Navy," has been cruising through England and Scotland during the past nine months, showing by means of animated photographs how a lad is trained from his entry and becomes an efficient bluejacket. In each town it has been received with great enthusiasm, and the Press have given it all commendation and encouragement, recognising the patriotic sentiment it draws forth and the vast amount of good it must be doing in showing what very few people have opportunities of witnessing, viz., "Life in the Royal Navy." It has further created a very strong impression in the minds of young lads, as, for instance, there were forty at Newcastle and eighteen at Sheffield applied to join the Navy after having seen it; thus it may be almost looked upon as a national recruiting agent. The lecture

is to be given in the afternoons and evening at the Polytechnic, Regent-street, commencing Saturday afternoon next, October 14.

\* \* \*

*Shamrock*, the yacht which is endeavouring to wrest the America Cup from the possession of Brother Jonathan, was photographed before her departure from New York by Messrs. G. West & Son. A reproduction of the photograph is published by Messrs. Marion & Co. of Soho-square. There should be a very large sale for this picture, as the interest in the struggle appears to be world-wide.

\* \* \*

THE well-known photographer, Mr. A. H. Fry, of the Royal Pavillion Studio, Brighton, sends us his twenty-four-page catalogue of photographs, the subjects comprising royalty, political, clerical, dramatic, educational, literary, musical, and sporting celebrities, cathedrals, abbeys, college chapels, churches, schools and public institutions, country mansions, and places of interest. The catalogue is very nicely arranged. We often wonder that such a comparatively small number of photographers take the trouble to catalogue their photographs of celebrities and prominent people: the practice should prove both useful and remunerative.

\* \* \*

THE Hon. Secretary of the Hackney Photographic Society asks us to notify intending contributors to the Hackney Exhibition who have photographs at either the Royal or the Salon Exhibitions now open, that they may have their photographs collected free of charge by the Hackney Society. Entries for the latter Exhibition close on the 21st inst.

\* \* \*

We have often objected to the term "photograph taken in the dark" applied to the interesting results obtained by Dr. W. J. Russell by means of the exposure of a sensitive plate to the exhalations from various metals and inorganic bodies, and subsequent development, and we are glad to see that the learned Doctor himself is now taking exception to the misnomer. He thus writes to last week's *Nature*: "I see in your issue of September 21 (p. 513) the statement that I am to lecture at the Royal Victoria Hall on "Photographs Taken in the Dark." I beg to say that the title I gave for my lecture was "Pictures Taken on a Photographic Plate in the Dark." I suppose the authorities at the Hall consider the titles identical. I do not." Neither, of course, does any one with a knowledge of the subject. However, if Dr. Russell's valuable experiments and results are not strictly photographic in the sense commonly understood, they at least throw many new and instructive lights on the susceptibility of the silver haloids to reduction by various causes.

\* \* \*

OUR contemporary, the *Pharmaceutical Journal*, gives particulars of a radiograph of an injected full-term foetus, which has been taken by Mr. F. H. Glew, chemist and druggist, Clapham, and which is said to be a remarkable example of the valuable results that can now be obtained by the use of the Röntgen rays. The foetus was injected by Mr. Charles Ind, of St. Thomas's Hospital, with mercury, the fluid being introduced by means of a hypodermic needle, connected by stout

rubber tubing to a funnel capable of holding two fluid ounces, and elevated above the level of the needle, in a suitable holder. The radiograph was taken directly the injection was finished, so as to prevent the mercury gravitating to the lowest level. The subject was arranged on a piece of thin cardboard over a Thomas Al plate, and the focus tube fixed over the middle of the plate, with the radiant point twenty-four inches distant. An exposure of twenty minutes was given, with a current of three amperes through a ten-inch Appa's coil. In the radiograph, the aorta, left side of the heart, kidneys, and spleen are readily recognisable, and the vessels of the neck and extremities are especially clear.

### THE FUTURE OF FILM PHOTOGRAPHY.

WITH the advent of new claimants to favour in the form of emulsions supported on other surfaces than glass, it is opportune to inquire what is likely to be the future of flexible films. The advantages of a support other than glass have been insisted upon again and again—reduced weight, no breakage, absence of halation, printing from either side of the negative—but the fact remains that, if the question of films *versus* glass turns up among half-a-dozen practical photographers who know what they are talking about, the consensus of opinion will be something like this: Yes, theoretically glass is doomed, but in practice we find it so much more convenient and certain that we prefer to put up with its alleged disadvantages. This, we say, is the kind of opinion that one gets from practical men who want negatives when they expose plates and want a good negative every time. They are ready to admit that glass has not a few disadvantages; and so, it is also urged, have the paper or celluloid films which seek to replace it.

The chief objection—and an extremely reasonable one—is the absence of a really light and compact dark slide for holding the sensitive film. Film-holders there are, it is true, but they are most of them irritating in use, and, when added to the weight of the film itself, very considerably discount the gain in lightness, which is a distinguishing feature in the argument for films. Then, in the larger sizes, it is difficult to ensure the film lying flat. Cut films, it seems to us, occupy just at present the unfortunate position of being before their time. They stand in need of a specially constructed light and thin dark slide, in which the film can be held taut and flat without such cumbrous makeshifts as backing cards, tacky supports, sheaths, or the other devices hitherto in vogue.

A form of slide which suggests itself to us as a possible type is one in which one end of the film can be clasped in a spring clip, extending across the base of the slide, and the other likewise inserted in a similar clip fixed in the upper end, and capable of a slight adjustment sufficient to stretch the film flatly in the focal plane. Considering the truly marvellous ingenuity displayed in the construction of photographic apparatus, it is not unreasonable to believe that some such device as we have roughly outlined may be obtainable at no distant date. It ought to be practicable to construct dark slides to take two paper or celluloid films, back to back and separated by a piece of thin card, in such a fashion as to greatly diminish the thickness of the slide. As soon as it is a certified fact that twelve film slides occupy only the space of, say, six plate slides, one of the greatest obstacles to the general adoption of films will have been removed.

It must be realised, too, that in the after-processes of development, fixing, and washing, all that is possible must be done to smooth the photographer's path. It cannot be denied that special difficulties, or perhaps we ought to say, special inconveniences, attend the use of films at these stages, and this must be taken into consideration alongside of another fact that photographers, when they take up a new process, are exceedingly prone to work it exactly as they did the one which they discarded for it. The troubles which attended the change from albumen to gelatino-chloride are evidences of this. Disappointment is likely to ensue when it is found that films cannot be treated quite in the rough and ready fashion that a plate can, and that those old and perchance forgotten evils, frilling or blisters, may arise through the neglect of precautions which the perfection of dry plates has long rendered unnecessary.

The washing of film negatives is a point which those interested in exploiting films might well consider. It is difficult to scamp the washing of a lot of negatives provided they are somehow or other arranged in moving water. Give them a reasonable time and they are pretty sure to be freed from hyposulphite; but in the case of films there is the same danger as with prints, that they will be left to soak in clots, or that, when washed in a "washer," they may get damaged; and, while a spoilt print only means the trouble of taking another, a spoilt negative may mean, and generally does, a good deal more. For this reason we are inclined to think that a negative film-washer of good design is a piece of apparatus of which there is need.

**Lightning Photographs.**—This subject continues to attract attention among the readers of *Nature*, and in the last issue for September will be found an illustration from a photograph of a very interesting character taken in Johannesburg. Mr. C. E. Stromeyer, who sends the photograph, thinks it indicates that the camera moved during exposure, as there are nine distinct lightning flashes, all of identical shape. Doubt is thrown upon the existence of ribbon lightning at all, while Mr. F. H. Glew draws attention to the "Clayden effect," described by him before the Royal Photographic Society in the earlier part of this year. This effect, it may be remembered, explains the appearance of so-called dark flashes which that writer believes also not to have an objective existence, but to be produced by the reversal of image produced on a plate "fogged" by a previous exposure to light. Mr. Glew refers to photographs of a four-inch spark, and the reversal effect producible at will by previously exposing the plate to the light from a piece of white cardboard illuminated by burning magnesium wire. This exposure is made both before and after the photographing of the spark image; but it is in the latter case only that the reversal appears.

**Photography and Telegraphy.**—According to the Vienna correspondent of the *Times*, photography is assisting in the making of a revolution in telegraphing. Telegraphing took place between Berlin and Buda Pesth at the rate of no less than 220 words in ten seconds. The result of this trial upon the minds of the experts who were present was distinctly favourable. The mode of working was as follows: A perforated roll of paper similar to that at present in use is employed for the despatch of the message, which is made visible and fixed photographically at the receiving end of the wire. Instead of the dashes and dots of the Morse alphabet, there are rising and falling strokes starting from a horizontal line. The receiver consists of a telephone fitted with a small concave mirror, upon which are reflected, in the form of streaks of light, the impulses marked on the membrane. By an ingenious arrangement, reminding one of cinematograph work, the streaks of light reflected upon the

mirror are reproduced upon a roll of sensitised paper, thus giving a narrow oblong picture, which, under the present stage of the invention, is developed and fixed like an ordinary photograph.

**The Relic of Andrée.**—The buoy marked Andrée Expedition, which was found by a Norwegian vessel on the north coast of King Charles Island in September last, was opened one day last week at Stockholm. That was carefully done in the presence of several experts and ministers, and it was found that the buoy was what was termed the North Pole buoy, which the explorer was to have dropped when passing the Pole. In it was found some sea sand and some water, and in an inner tube was a coating which seemed at first to resemble paper, but a microscopical examination showed that it was only a growth of algae. Professor Nathorst expressed the opinion that the buoy could not have been carried from the Pole to King Charles Island. The general impression was that the buoy had been thrown out empty—possibly to lighten the balloon. It has been decided that a search will be made at King Charles Island next year. There seems to be no doubt that this is a genuine relic of Andrée's Expedition, but it unfortunately leads to no clue as to its fate.

**Separation of the Haloids.**—An article by M. Bougalt on this subject given in the *Chemical News*, as abstracted from the *Journal de Pharmacie et de Chimie*, contains some practical remarks, although they do not possess, as the writer imagines, the element of novelty, for only last week we quoted in our LANTERN SUPPLEMENT Professor Valenta's method, which is identical in principle, though not so full of instructions as to precautions to be taken. M. Bougalt, alluding to the many methods that have been proposed for making these estimations, says the text-books suggest "at best an indirect method, which comprises the three following operations: (1.) Precipitation by nitrate of silver and weighing the mixed precipitate; (2.) Conversion of the whole of the argentic precipitate into chloride of silver, and weighing the chloride of silver formed; (3.) Separation of the iodine either by precipitation with chloride of palladium, or by setting it free by means of an oxidising agent, and removing it by means of sulphide of carbon. In the case of the presence of two halogens only, it is evident that the two first operations will suffice." He then points out, with regard to the second operation, the simplicity and exactitude of the method we allude to, which we have not found "described anywhere." He uses absolutely pure granulated zinc, which can be obtained commercially, and, taking a small quantity of the argentic precipitate, adds to it about fifty times its weight of ten per cent. sulphuric acid, and gradually adds portions of zinc till about the weight of the precipitate has been used (each addition to be dissolved before adding a further quantity. It is indispensable that the whole of the zinc be dissolved.) Then filter and wash with distilled water. The precipitate collected is pure silver. The filter and precipitate are ignited in a crucible, and, allowing for the ash, the actual weight of silver is found. From this the proportions of the respective bromide and chloride, or iodine and chlorine, can be calculated by the usual methods. M. Bougalt states that he has obtained absolutely exact results when working with mixtures containing forty or fifty per cent. of iodine, with only five or six per cent. of chlorine.

**Another Death by Cyanide of Potassium.**—In our issue of last week we alluded to a suicide by means of cyanide of potassium, purchased for alleged photographic purposes, and incidentally mentioned that deaths from this poison were of much less frequent occurrence than formerly. Singularly enough there has been another case since. It appeared that the deceased was a silver-smith, and had been arrested for felony, and was searched at the Marlborough-mews Police Station. On him was found a lump of white material, which he told the police was "sugar," and he was allowed to keep it. When in the cell he commenced to eat it, and almost immediately fell to the ground. When removed to the Middlesex Hospital, the doctors found that he had poisoned himself

with cyanide of potassium. That salt is used more by silversmiths and the like than it is at the present time by photographers, and still more largely by electro-platers. Sugar and the cyanide are not much alike in appearance, and it seems a little remiss on the part of the police that the difference was not noticed. They certainly could not have smelt it.

**The City Art Gallery.**—Slowly the Corporation of the City of London are acquiring a valuable Art collection. We learn that the picture, painted by Mr. A. C. Gow, R.A., representing the brilliant scene outside St. Paul's Cathedral on the occasion of the Thanksgiving Service on Jubilee Day, 1897, and which was shown in the last Royal Academy Exhibition, is to be presented to the Lord Mayor as representing the Corporation, and hung in the Art Gallery of Guildhall on Wednesday next, the 18th inst. The donor is Mr. Henry Clark, and this picture is an excellent *souvenir* of that memorable event in the City, as well as a fine work of Art. The Corporation are gradually acquiring an Art collection that it is hoped will be a credit to the first city in the world. A really good Fine Art Gallery in the heart of the busy City might almost be compared to an oasis in the desert.

**Process Businesses.**—We see from the City News and Commercial Intelligence of a daily contemporary that the Directors of Carl Hentschell, Limited, the well-known process workers, have acquired the whole of the shares of the Meisenbach Company, Limited. The capital of the latter Company is 10,000*l.*, fully paid up. These two Companies are amongst the best process workers we have in this country, and are not amongst those who are "cutting the trade" in the matter of prices.

### THE TONING OF BLACK IMAGES.

ALTHOUGH every one recognises that there is a fashion in dress, it is not so generally recognised that we have fashions or cycles in almost everything else as well. Years ago croquet was the game that was played on private and public lawns, but this was ousted by lawn tennis, and now the years have revolved, and croquet seems likely to hold its own again.

As in our games and sports, so in our hobby of photography. Years ago black images were all the rage, then came the red-brown tones, mostly of uranium-toned bromides, then a wave of black, flat, lifeless tones ensued, and now it would almost seem that we were going to revert to browns, though of a somewhat darker shade than before.

The numerous "gaslight" bromide papers on the market, and the formulae for obtaining warm tones, seem to point to a tendency to the warmer tone, which, though it can be obtained with certainty and ease when working with one negative under absolutely constant conditions, is not so easy when numerous negatives are printed from, and only one or two prints required from each.

The following methods, which are by no means new, but merely old ones modified as experience has proved, are the most satisfactory for toning black images, whether on paper or glass, in the form of lantern slides or transparency.

The most usual method of obtaining reddish-brown and sepia tones is by means of a uranium salt and ferridcyanide of potassium. The chemical action which takes place in toning is, of course, the formation of ferrocyanide of silver and ferrocyanide of uranium, the latter being precipitated upon the image in a form insoluble in water, but readily soluble in an alkali; hence it is usual to acidify the toning solution, and also to acidify the washing waters. The best acid is undoubtedly acetic, because it has no action on the silver image or upon the toned image.

In all the toning formulae which I shall treat of there is one common solution, that of the ferridcyanide, which is best made up in a one per cent. solution with ten per cent. of glacial acetic acid.

The uranium salt generally used is the nitrate, but it is better to

use the acetate, and a one per cent. solution of this, with ten per cent. of glacial acetic acid, forms the necessary stock solutions.

The tones obtained by these solutions varies somewhat according to the proportion of the ferridcyanide and uranium, as there are two distinct ferrocyanides of uranium, which are precipitated the more readily when the above solutions are mixed in definite proportions.

For sepia tones an admixture of one part of ferridcyanide solution and two parts of uranium solution is the best; for reddish-brown tones, one part of ferridcyanide solution and one and a half parts of uranium solution; whilst for bright red tones equal parts of ferridcyanide and uranium solutions should be used.

There are certain precautions to be taken when using these solutions, notably, the absence of hyposulphite, and it is advisable to treat the print or image to a bath of ammonium persulphate (one per cent.) before toning. Then, again, in toning for reddish-brown or bright red, the prints should be allowed to lie perfectly still in the dish, or otherwise some of the image, which is in a readily soluble state, may be dissolved.

Considerable variation of tone can be produced by varying the time of immersion, as, for instance, by merely immersing a print in the bath destined for bright red tones for a short time, a warm sepia is obtained, but the image is certainly more liable to change when in this condition than if the proper bath is used, and the baths are so compounded as to give the correct tone, no matter how long the prints are immersed.

As I have already pointed out, these images are soluble in alkalies, and therefore it is advisable to a great extent to acidify the washing waters with acetic acid.

All the above, and the following toning solutions, are more or less sensitive to light, and should therefore be kept in the dark.
